‘A História depende da nossa forma de pensar o futuro’

Como se escreve a História, hoje em dia? Num mundo desprovido de horizonte utópico, a historiografia é hoje em dia dominada pela noção de memória, explica o historiador Enzo Traverso numa obra sobre as violências do século XX.

CENTENNIAL REVIEW

Chronic non-communicable diseases

N. UNWIN* and K. G. M. M. ALBERTI†

*School of Population and Health Sciences, University of Newcastle upon Tyne, William Leech Building, Framlington Place, Newcastle upon Tyne NE2 4HH, U.K.
†Department of Endocrinology and Metabolic Medicine, Imperial College London, St Mary's Hospital, Mint Wing, Praed Street, London W2 1NY, U.K.

Received 12 June 2006, Accepted 13 June 2006

Chronic non-communicable diseases (NCD) account for almost 60% of global mortality, and 80% of deaths from NCD occur in low- and middle-income countries. One quarter of these deaths — almost 9 million in 2005 — are in men and women aged <60 years. Taken together, NCD represent globally the single largest cause of mortality in people of working age, and their incidences in younger adults are substantially higher in the poor countries of the world than in the rich. The major causes of NCD-attributable mortality are cardiovascular disease (30% of total global mortality), cancers (13%), chronic respiratory disease (7%) and diabetes (2%). These conditions share a small number of behavioural risk factors, which include a diet high in saturated fat and low in fresh fruit and vegetables, physical inactivity, tobacco smoking, and alcohol excess. In low- and middle-income countries such risk factors tend to be concentrated in urban areas and their prevalences are increasing as a result of rapid urbanization and the increasing globalisation of the food, tobacco and alcohol industries.

Because NCD have a major impact on men and women of working age and their elderly dependents, they result in lost income, lost opportunities for investment, and overall lower levels of economic development. Reductions in the incidences of many NCD and their complications are, however, already possible. Up to 80% of all cases of cardiovascular disease or type-2 diabetes and 40% of all cases of cancer, for example, are probably preventable based on current knowledge. In addition, highly cost-effective measures exist for the prevention of some of the complications of established cardiovascular disease and diabetes. Achieving these gains will require a broad range of integrated, population-based interventions as well as measures focused on the individuals at high risk. At present, the international-assistance community provides scant resources for the control of NCD in poor countries, partly, at least, because NCD continue to be wrongly perceived as predominantly diseases of the better off. As urbanization continues apace and populations age, investment in the prevention and control of NCD in low-and middle-income countries can no longer be ignored.

Chronic Diseases 1

The burden and costs of chronic diseases in low-income and middle-income countries

Dele O Abegunde, Colin D Mathers, Taghreed Adam, Monica Ortegon, Kathleen Strong

This paper estimates the disease burden and loss of economic output associated with chronic diseases—mainly cardiovascular diseases, cancer, chronic respiratory diseases, and diabetes—in 23 selected countries which account for around 80% of the total burden of chronic disease mortality in developing countries. In these 23 selected low-income and middle-income countries, chronic diseases were responsible for 50% of the total disease burden in 2005. For 15 of the selected countries where death registration data are available, the estimated age-standardised death rates for chronic diseases in 2005 were 54% higher for men and 86% higher for women than those for men and women in high-income countries. If nothing is done to reduce the risk of chronic diseases, an estimated US$84 billion of economic production will be lost from heart disease, stroke, and diabetes alone in these 23 countries between 2006 and 2015. Achievement of a global goal for chronic disease prevention and control—an additional 2% yearly reduction in chronic disease death rates over the next 10 years—would avert 24 million deaths in these countries, and would save an estimated $8 billion, which is almost 10% of the projected loss in national income over the next 10 years.

Conflict and Emerging Infectious Diseases

Michelle Gayer,* Dominique Legros,* Pierre Formenty,* and Maire A. Connolly*

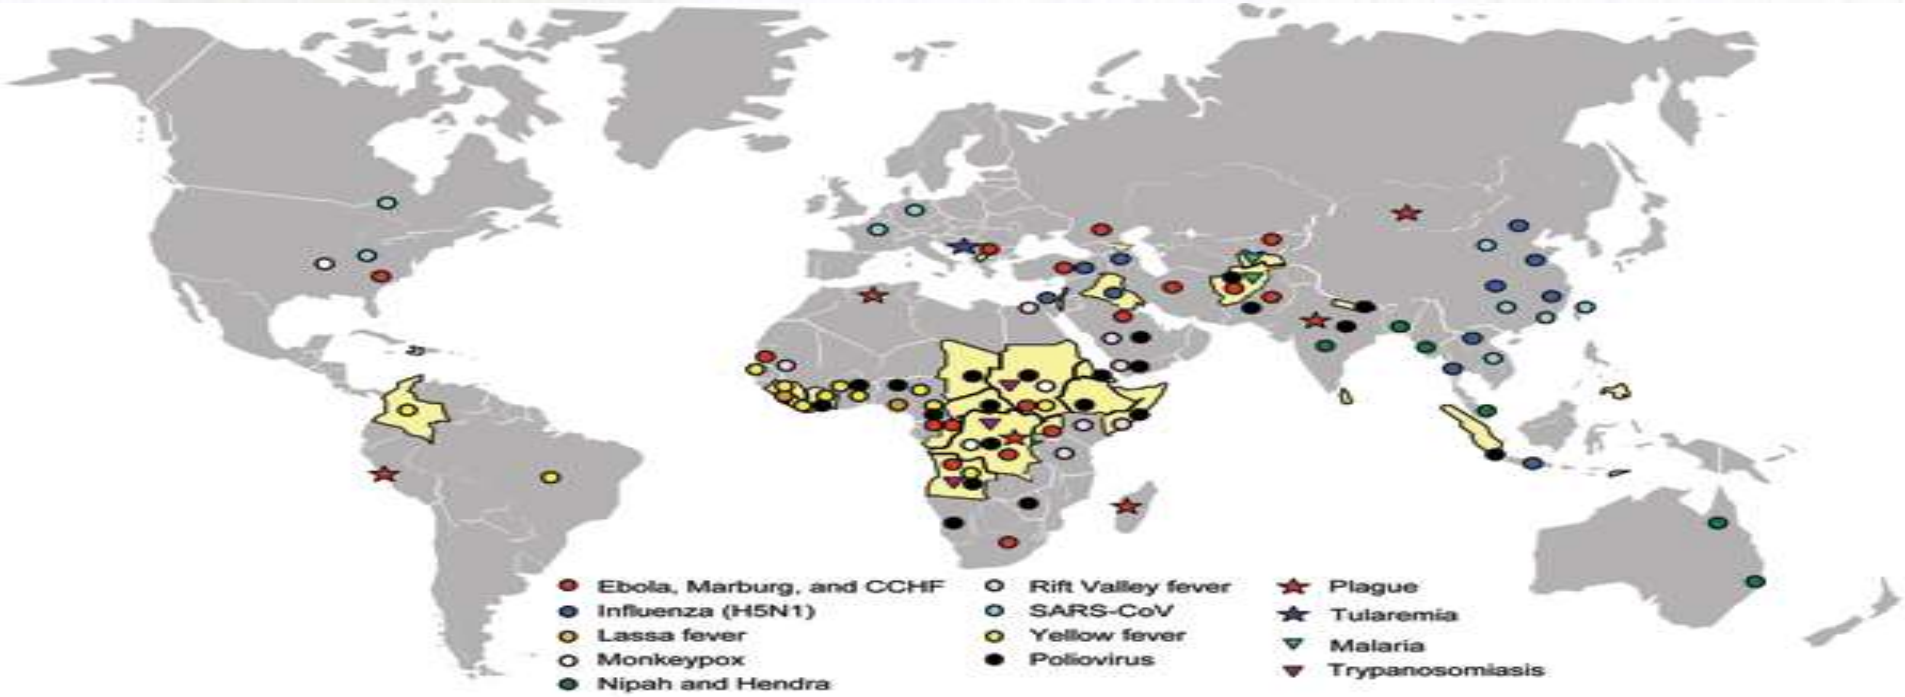

Figure. Geographic distribution of recent emerging or reemerging infectious disease outbreaks and countries affected by conflict, 1990–2006. Countries in yellow were affected by conflict during this period (source: Office for the Coordination of Humanitarian Affairs, World Health Organization, www.reliefweb.int/ocha_ol/onlinehp.html). Symbols indicate outbreaks of emerging or reemerging infectious diseases during this period (source: Epidemic and Pandemic Alert and Response, World Health Organization, www.who.int/csr/en). Circles indicate diseases of viral origin, stars indicate diseases of bacterial origin, and triangles indicate diseases of parasitic origin. CCHF, Crimean-Congo hemorrhagic fever; SARS-CoV, severe acute respiratory syndrome coronavirus.

Le dossier du bioterrorisme

BIOTERRORISME

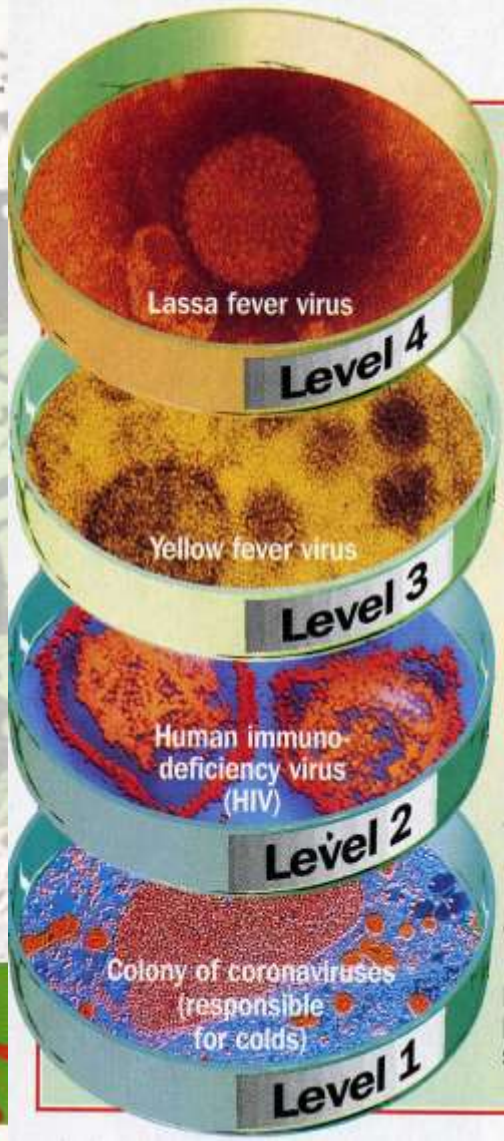
QUATORZE AGENTS DE BIOTERRORISME OU DE GUERRE BIOLOGIQUE

NOM D'USAGE COURANT	NOM SCIENTIFIQUE DE L'AGENT	NATURE DE L'AGENT	NOM DE LA MALADIE	MODE D'INFECTION	CONTAGIOSITÉ	MORTALITÉ	SYMPTÔMES
Anthrax, charbon	"Bacillus anthracis"	Bactérie (Mûrier sous microsc.) Souches plus ou moins virulentes	Charbon pulmonaire (contenu des traces de laine ; le charbon cutané est le plus souvent bénin)	Par inhalation des spores	Nulle	Très élevée	Temps d'incubation généralement court (deux à quatre jours). Premiers symptômes comparables à ceux d'une forte grippe, puis rapidement, fièvre, apparition de difficultés respiratoires, gonflement douloureux sur la poitrine et le cou
Botulisme	"Clostridium botulinum"	Toxine de la bactérie	Botulisme	Par ingestion (ou inhalation de la toxine cristallisée)	Aucune	Forte (quelques nanogrammes de toxine suffisent)	Vision brouillée, difficulté à avaler, faiblesse puis paralysie musculaire
Brucellose	"Brucella suis"	Bactérie	Brucellose	Par ingestion ou infection par plaie cutanée	Rare	Très faible (depuis l'antibiotique)	N'apparaissent qu'après une longue période d'incubation. Fièvre, transpirations, douleurs musculaires. Provoque parfois des troubles chroniques
Choléra	"Vibrio cholerae"	Bactérie (Vibrion sous microsc.)	Choléra (infection de l'intestin grêle)	Par ingestion d'eau ou de nourriture contaminées	Oui	Moyenne	Après incubation de 12 à 48 heures, diarrhée, déshydratation, vomissements, déshydratation générale
Ebola	Virus d'Ebola	Virus (Filovirus)	Fièvre hémorragique d'Ebola	Par contact direct avec sécrétions ou fluides contaminés ou par inhalation	Très grande	Entre 70 % et 90 %. Dépend de la souche	Une semaine d'incubation, symptômes grippaux puis hémorragies
Encéphalite du Venezuela	Virus EEV	Virus à ARN	Encéphalomyélite équine du Venezuela	Dans la nature, par piqûre de moustique		Agent incapacitant. Risque d'effets permanents sur le système nerveux central et périphérique. Mortalité faible	Maladie grave, forte fièvre, nausées, céphalées, diarrhée
Fièvre Q	"Coxiella burnetii"	Rickettsie	Fièvre Q	Par inhalation. Une seule bactérie peut créer la maladie	Forte	Agent incapacitant. Mortalité très faible en cas de traitement	D'abord comparables à ceux d'une grippe avec douleurs articulaires et musculaires, douleurs de la face et de la tête, forte fièvre
Marburg	Virus de Marburg (Marburg)	Filovirus	Fièvre hémorragique de Marburg	Par contact direct avec animaux ou humains contaminés	Très élevée	Très élevée	D'abord des ecchymoses, puis hémorragie générale
Morve	"Burkholderia mallei"	Bactérie	Morve	Par contact direct avec animaux malades (chiens, chats...)	Modérée	De modérée à élevée	Fièvre, douleurs musculaires, risque de pneumonie
Peste	"Yersinia pestis"	Bactérie	Peste pulmonaire (la peste bubonique n'est plus considérée comme une arme)	Habituellement transmise du rat et l'homme par piqûres de puce. L'AMCS a développé un aérosol	Très élevée (par inhalation)	Très élevée	Fièvres, symptômes comparables à une grippe puis très rapidement pneumonie (sang), pneumonie
Salmonelle	"Salmonella enterica typhimurium"	Entérobactérie	Salmonellose (la typhoïde est provoquée par une autre salmonelle)	Par ingestion	Non	Agent incapacitant. Mortalité rare	Diarrhée et vomissements, prostration, fièvre
Staphylocoque doré	Entérotoxine staphylococcique B	Toxine de la bactérie	Septicémie	Par ingestion ou par inhalation	Non	Agent incapacitant. Mortalité faible	D'abord comparables à une grippe, puis très forte fièvre, douleurs musculaires, diphtérie, toux
Tularémie	Francisella tularensis	Bactérie	Tularémie	Par inhalation, ingestion, aérosolisation, ou via moustiques et animaux. Une centaine de germes par individu suffisent	Aucune	Agent incapacitant. Mortalité 35 % en l'absence de soins	Fièvres, nausées, diarrhées, fièvre pendant deux à quatre semaines
Variole	"Variola major"	Virus	Variole	Moins de cinq particules suffisent pour infecter des personnes. Par contact ou inhalation	De modérée à élevée (par inhalation ; il peut suffire d'une goutte de toux)	De modérée à élevée (plus élevée chez ceux qui sont trop jeunes pour avoir été vaccinés contre la variole ou chez les immunodéprimés)	Incubation de deux semaines, puis symptômes de fortune grippe, qui se transforment en pustules

Botulisme

Brucellose

Choléra



The virus hierarchy

LEVEL 4: eg: Lassa fever, Marburg, Ebola Zaire viruses
No known cure. Highly infectious. Fast acting. High mortality rates.

LEVEL 3: eg: Yellow fever, dengue haemorrhagic fever virus
Easily contracted. Potentially fatal, and serious when not fatal.

LEVEL 2: eg: HIV (Aids)
Difficult to contract. Easily destroyed. Serious, possibly fatal.

LEVEL 1: eg: cold viruses
Relatively innocuous – not fatal.

VIRUSES are infectious packages of genetic material (DNA or RNA) in a protein coat. There is debate about whether they should be considered alive: their only activity is to take over living cells of other organisms, without which they cannot survive. Despite these limitations, viruses plague us: flu, colds, glandular fever, polio, some eye infections, possibly some cancers – all are viruses.

EXTENT OF CRISIS REVEALED

20,000 die each day

Matt Wade

Extreme poverty claimed more than 20,000 lives yesterday with common illnesses, including chest infections and diarrhoea, accounting for a third of the victims. Another 20,000 people are expected to die from treatable illnesses today - and again tomorrow.

The three biggest killers - respiratory infections, diarrhoea and malnutrition - took nearly 16,000 lives, the majority of them children under the age of five.

More than 6000 of the deaths yesterday were in just four African countries: Nigeria, the Democratic Republic of Congo, Ethiopia and Tanzania.

Penny O'Connor, 35, an Australian aid worker in Ethiopia with Médecins Sans Frontières, said her biggest frustration was the lack of affordable medicines to treat illnesses such as malaria, HIV/AIDS and kala azar - a parasitic disease that can be fatal if left untreated.

"Kala azar and malaria are curable, HIV/AIDS is treatable, yet the majority of Ethiopians do not have access to basic health care or life-saving drugs so they die," she told the Herald.

About 270 million people - 13 times the population of Australia - have died from poverty-related causes since 1990.

Leaders from the world's eight wealthiest countries - the G8 - will discuss increased aid spending at a meeting in Scotland next week.

The group is under pressure to provide more meaningful assistance, especially for Africa.

The catastrophe is expected to continue ...

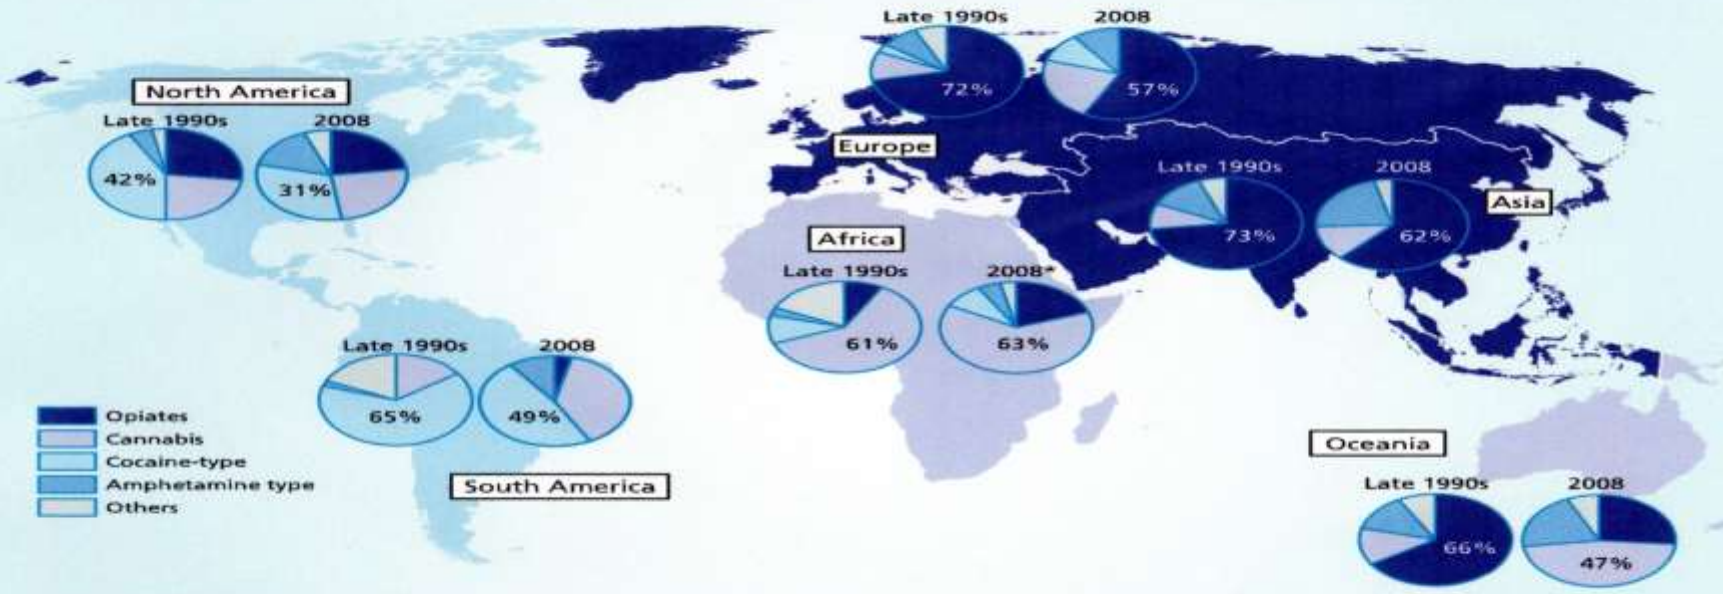
WORLD DRUG REPORT 2010

Main problem drugs as reflected in treatment demand, by region, from the late 1990s to 2008 (or latest year available)



Sources: UNODC, Annual Reports Questionnaire Data/ORCA and National Government Reports

Notes: Percentages are unweighted means of treatment demand from reporting countries. Number of countries reporting data for 2008: Europe (45); Africa (28); North America (3); South America (24); Asia (42); Oceania (2). Data generally account for primary drug use. Polydrug use may increase totals beyond 100%. * Treatment data dating back more than 10 years were removed from the 2008 estimates and therefore caution should be taken comparing the data from 2008 with previous years. The boundaries and names shown and the designations used on this map do not imply official endorsement or acceptance by the United Nations.

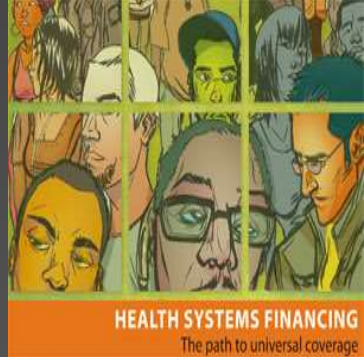
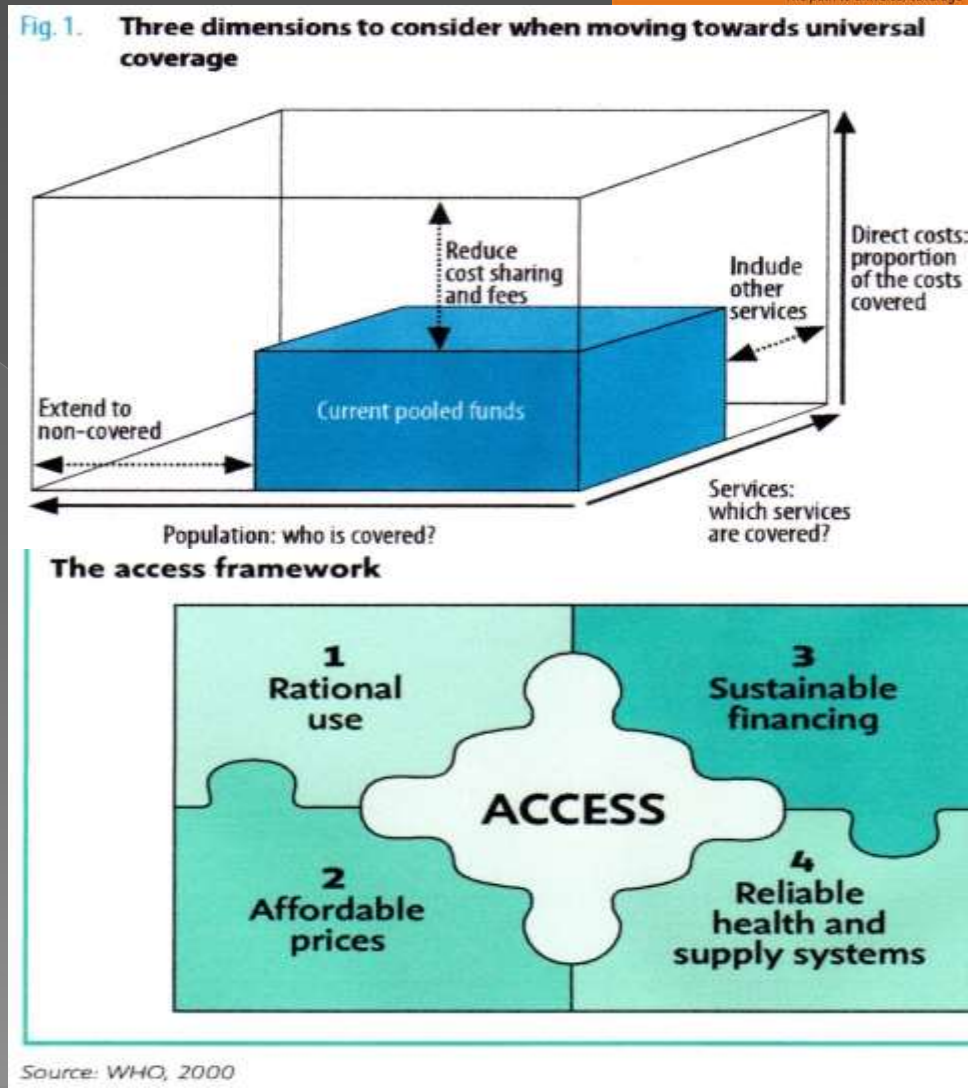
CONSTATAÇÕES da REALIDADE



- " … existiu uma previsão supostamente realista segundo a qual no ano 2.000 nenhum país, ou sequer qualquer dos seus cidadãos, viesse a ter um nível de saúde inferior ao aceitável … a Saúde Pública é a arte de saber aplicar a ciência num determinado contexto político para reduzir as desigualdades na prestação dos cuidados de saúde enquanto se assegura simultaneamente a melhor saúde possível a um maior número de pessoas … a proporção do PNB alocado à Saúde deixou de crescer, e tem mesmo vindo a diminuir à escala planetária … constatando-se que do total do dispêndio financeiro em investigação de novos fármacos, somente 10% corresponde às doenças que são responsáveis por 90% da mortalidade em todo o Mundo … existindo cerca de 2 biliões de pessoas sem qualquer acesso aos medicamentos considerados essenciais … calcula-se ainda que o desperdício orce entre 20 a 40 % do total daquilo que se gasta com a Saúde … somente 20 % das pessoas têm uma cobertura social adequada, sendo calculado que para tal seriam apenas necessário cerca de 60 USD / pessoa / ano, em contraste com os actuais 20 USD, sendo certo que cerca de 50 % desta despesa é suportada directamente pelo próprio cidadão … " *(WHO Reports, 1998, 2004 e 2010)*



Building of the global movement for health equity: from Santiago to Rio and beyond

Michael Marmot, Jessica Allen, Ruth Bell, Peter Goldblatt

Health inequalities are present throughout the world, both within and between countries. The Commission on Social Determinants of Health drew attention to dramatic social gradients in health within most countries and made proposals for action. These inequalities are not inevitable. The purpose of this article is to report on activity that has taken place worldwide after the report by the Commission on Social Determinants of Health. First, we summarise the global situation. Second, we summarise an interim report of the emerging findings from an independent review of social determinants and the health divide, which was commissioned by the WHO European region. The world conference on social determinants of health will be held in Rio de Janeiro, Brazil, in October, 2011. This summit provides an opportunity to galvanise support, prioritise action, and respond to the call by the Commission on Social Determinants of Health for social justice as a route to a fair distribution of health.

"Social Injustice is killing on a grand scale"

"A toxic combination...of poor social policies and programmes, unfair economic arrangements, and bad politics...is responsible for the fact that a majority of people in the world do not enjoy the good health that is biologically possible."

The Intolerable Burden of Malaria: A New Look at the Numbers

Supplement to Volume 64(1) of the *American Journal of Tropical Medicine and Hygiene*

Edited by Joel G Breman, Andréa Egan, and Gerald T Keusch.

The Economic Burden of Malaria

John Luke Gallup* and Jeffrey D. Sachs.

Center for International Development, Harvard University, Cambridge, Massachusetts

Abstract

Malaria and poverty are intimately connected. Controlling for factors such as tropical location, colonial history, and geographical isolation, countries with intensive malaria had income levels in 1995 of only 33% that of countries without malaria, whether or not the countries were in Africa. The high levels of malaria in poor countries are not mainly a consequence of poverty. Malaria is geographically specific. The ecological conditions that support the more efficient malaria mosquito vectors primarily determine the distribution and intensity of the disease. Intensive efforts to eliminate malaria in the most severely affected tropical countries have been largely ineffective. Countries that have eliminated malaria in the past half century have all been either subtropical or islands. These countries' economic growth in the 5 years after eliminating malaria has usually been substantially higher than growth in the neighboring countries. Cross-country regressions for the 1965–1990 period confirm the relationship between malaria and economic growth. Taking into account initial poverty, economic policy, tropical location, and life expectancy, among other factors, countries with intensive malaria grew 1.3% less per person per year, and a 10% reduction in malaria was associated with 0.3% higher growth. Controlling for many other tropical diseases does not change the correlation of malaria with economic growth, and these diseases are not themselves significantly negatively correlated with economic growth. A second independent measure of malaria has a slightly higher correlation with economic growth in the 1980–1996 period. We speculate about the mechanisms that could cause malaria to have such a large impact on the economy, such as foreign investment and economic networks within the country.

PRELIMINARY DRAFT FOR DISCUSSION

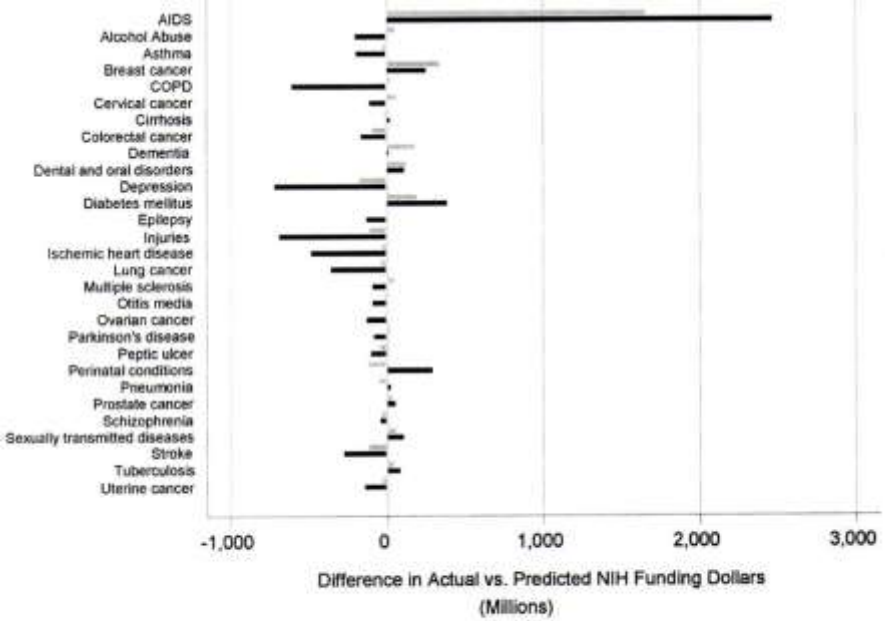

Figure 1. Ten-year Comparison of Differences Between Actual and Expected Disease-Specific NIH Funding Relative to US Burden of Disease in DALYs. A comparison of differences between actual and expected funding values as predicted by **DALYs burden alone in 1996 (light blue)** and **2006 (navy)**. Negative values reflect actual funding dollars less than expected and positive values represent actual funding dollars more than expected.
doi:10.1371/journal.pone.0016837.g001

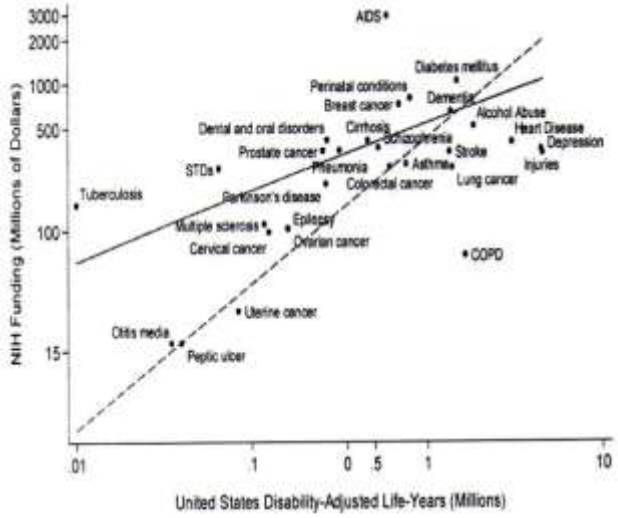

Figure 2. NIH Funding in 2006 and US Disease Burden in DALYs in 2004 for 29 Common Medical Conditions. The **solid line** represents the results of a traditional multivariable analysis, showing the relationship between US disease-specific DALYs burden and actual 2006 NIH funding dollars. The **dashed line** projects NIH funding levels in a similar multivariable model that requires that a disease with no burden receives no funding (constrained model). Though the models produce similar results, several diseases that would be considered overfunded in one model are considered underfunded in the other. For example, cervical cancer appears to be overfunded relative to the dashed line, while it is underfunded relative to the solid one.

NIH Disease Funding Levels and Burden of Disease

Leslie A. Gillum[1], Christopher Gouveia[1], E. Ray Dorsey[3], Mark Pletcher[2], Colin D. Mathers[4], Charles E. McCulloch[2], S. Claiborne Johnston[1,2]*

1 Department of Neurology, University of California San Francisco, San Francisco, California, United States of America, 2 Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, California, United States of America, 3 Department of Neurology, Johns Hopkins University Medical Center, Baltimore, Maryland, United States of America, 4 Department of Health Statistics and Informatics, World Health Organization, Geneva, Switzerland

Abstract

Background: An analysis of NIH funding in 1996 found that the strongest predictor of funding, disability-adjusted life-years (DALYs), explained only 39% of the variance in funding. In 1998, Congress requested that the Institute of Medicine (IOM) evaluate priority-setting criteria for NIH funding; the IOM recommended greater consideration of disease burden. We examined whether the association between current burden and funding has changed since that time.

Methods: We analyzed public data on 2006 NIH funding for 29 common conditions. Measures of US disease burden in 2004 were obtained from the World Health Organization's Global Burden of Disease study and national databases. We assessed the relationship between disease burden and NIH funding dollars in univariate and multivariable log-linear models that evaluated all measures of disease burden. Sensitivity analyses examined associations with future US burden, current and future measures of world disease burden, and a newly standardized NIH accounting method.

Results: In univariate and multivariable analyses, disease-specific NIH funding levels increased with burden of disease measured in DALYs ($p = 0.001$), which accounted for 33% of funding level variation. No other factor predicted funding in multivariable models. Conditions receiving the most funding greater than expected based on disease burden were AIDS ($2474 M), diabetes mellitus ($390 M), and perinatal conditions ($297 M). Depression ($719 M), injuries ($691 M), and chronic obstructive pulmonary disease ($613 M) were the most underfunded. Results were similar using estimates of future US burden, current and future world disease burden, and alternate NIH accounting methods.

Conclusions: Current levels of NIH disease-specific research funding correlate modestly with US disease burden, and correlation has not improved in the last decade.

Table 2. Survival Gains in Resulting From Medical/Surgical Advances in Various Diseases

Condition	Treatment	Per-person survival gains (months)
Non-small-cell lung cancer	Chemotherapy	7
Node and breast cancer	Adjuvant chemotherapy	29
Coronary artery disease	Bypass surgery	50
Relapsed non-Hodgkin's lymphoma	Marrow transplant	92
Prophylaxis in persons with HIV/AIDS	Opportunistic infection prophylaxis: trimethoprim/sulfamethoxazole, azithromycin	3
HIV/AIDS	Antiretroviral therapy	160

Cost-Effectiveness Ratios for HIV Care and Screening for Other Medical Conditions

Intervention/Population	Agent	Cost/QALY*	Reference
HIV			
PCP/toxo prophylaxis	TMP/SMX	$ 2800	4
Antiretroviral therapy	EFV/ZDV/3TC	$11,700	5
Resistance testing	----------	$20,200	6
Inpatient screening	----------	$38,600	2
MAC prophylaxis	Azithromycin	$43,300	4
HIV screen: high-risk patients every 5 yrs	----------	$50,000	8
Other Conditions			
Breast cancer, women age > 50 yrs	Annual mammogram	$57,700	9
Colon cancer, age 50-85 yrs	Colonoscopy	$57,500	9
Diabetes, age > 25 yrs	FBS	$70,000	9

EXPERIMENTAL DRUGS ON TRIAL

A controversial lawsuit challenges the FDA's system of controlling access to experimental drugs and, some say, the scientific basis of drug approval

By Beryl Lieff Benderly

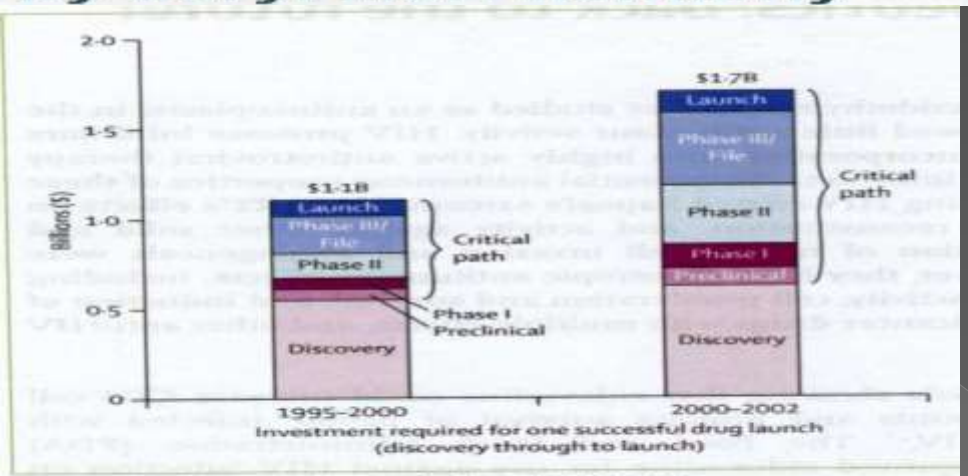

Figure 2: **Growing cost of successful drug development**
The cost of successful drug development increased 55% from 1995–2000 to 2000–02. Most of the rising costs are attributable to clinical trials. Reproduced with permission from reference 2.

RATIONAL USE OF MEDICINES

SUMMARY

- Worldwide, it is estimated that half of all medicines are inappropriately prescribed, dispensed or sold, and that half of all patients fail to take their medicine properly.
- An estimated two-thirds of global antibiotic sales occur without any prescription, and studies in Indonesia, Pakistan and India show that over 70% of patients were prescribed antibiotics. The great majority – up to 90% – of injections are estimated to be unnecessary.
- The inappropriate use of medicines is not only widespread, it is costly and extremely harmful both to the individual and the population as a whole. Adverse drug events rank among the top 10 causes of death in the USA and are estimated to cost that country between US$ 30 and US$ 130 billion each year.
- Growing resistance to antimicrobial medicines is a particularly serious challenge in countries at all economic levels, and results largely from inappropriate prescribing and use. For the treatment of malaria, chloroquine resistance is now established in 81 of the 92 countries in which the disease is endemic.
- Much greater use of evidence-based diagnostic and treatment guidelines by health professionals is needed.
- More effective monitoring and regulation of medicines, and public education and information are important components of a strategy for increased rational use.

- Por cada molécula aprovada para uso clínico, são investigadas 25 novos compostos, de entre aproximadamente 5.000 possíveis alternativas, durante cerca de 10 a 15 anos
- Somente 21,5 % das moléculas que entram em fase I de desenvolvimento chegam a ser comercializadas
- Custos triplicaram em 4 anos (1998-2001)
- Em 2007: 1,3 biliões de USD / molécula
- Em 2008: Investimento total (USA): 65.2 biliões de USD, contabilizando-se cerca de 2.900 compostos em investigação (300 para Doenças Raras, 750 para Doenças Neoplásicas, 277 para Doenças Cerebro/Cardio-Vasculares, e 109 para a SIDA)
- Em 2008: Existia um repositório de cerca de 100.000 moléculas que poderão ser futuramente investigadas, embora apenas 100 dos cerca de 3.000 alvos proteicos conhecidos a partir do Genoma Humano poderão permitir a síntese de novos medicamentos a curto/médio prazo
- Calcula-se que os medicamentos são responsáveis por cerca de 50 a 60% da redução da mortalidade presentemente verificada em todo o mundo, sendo mais acentuada nas Doenças Neoplásicas, Doenças Cerebro/Cardio-Vasculares e SIDA.

Abstract It is widely claimed that research to discover and develop new pharmaceuticals entails high costs and high risks. High research and development (R&D) costs influence many decisions and policy discussions about how to reduce global health disparities, how much companies can afford to discount prices for lower- and middle-income countries, and how to design innovative incentives to advance research on diseases of the poor. High estimated costs also affect strategies for getting new medicines to the world's poor, such as the advanced market commitment, which built high estimates into its inflated size and prices. This article takes apart the most detailed and authoritative study of R&D costs in order to show how high estimates have been constructed by industry-supported economists, and to show how much lower actual costs may be. Besides serving as an object lesson in the construction of 'facts', this analysis provides reason to believe that R&D costs need not be such an insuperable obstacle to the development of better medicines. The deeper problem is that current incentives reward companies to develop mainly new medicines of little advantage and compete for market share at high prices, rather than to develop clinically superior medicines with public funding so that prices could be much lower and risks to companies lower as well.

Drug development for neglected diseases: a deficient market and a public-health policy failure

Patrice Trouiller, Piero Olliaro, Els Torreele, James Orbinski, Richard Laing, Nathan Ford

There is a lack of effective, safe, and affordable pharmaceuticals to control infectious diseases that cause high mortality and morbidity among poor people in the developing world. We analysed outcomes of pharmaceutical research and development over the past 25 years, and reviewed current public and private initiatives aimed at correcting the imbalance in research and development that leaves diseases that occur predominantly in the developing world largely unaddressed. We compiled data by searches of Medline and databases of the US Food and Drug Administration and the European Agency for the Evaluation of Medicinal Products, and reviewed current public and private initiatives through an analysis of recently published studies. We found that, of 1393 new chemical entities marketed between 1975 and 1999, only 16 were for tropical diseases and tuberculosis. There is a 13-fold greater chance of a drug being brought to market for central-nervous-system disorders or cancer than for a neglected disease. The pharmaceutical industry argues that research and development is too costly and risky to invest in low-return neglected diseases, and public and private initiatives have tried to overcome this market limitation through incentive packages and public-private partnerships. The lack of drug research and development for "non-profitable" infectious diseases will require new strategies. No sustainable solution will result for diseases that predominantly affect poor people in the South without the establishment of an international pharmaceutical policy for all neglected diseases. Private-sector research obligations should be explored, and a public-sector not-for-profit research and development capacity promoted.

ABSTRACT

Over 7000 rare diseases, each <200,000 US residents, affect nearly 30 million people in the United States. Furthermore, for the 10% of people with a rare disease and for their families, these disorders no longer seem rare. Molecular genetics have characterized the cause of many rare diseases and provide unprecedented opportunities for identifying patients, determining phenotypes, and devising treatments to prevent, stabilize, or improve each disease. Rare disease research poses challenges to investigators requiring specific approaches to: (1) the design of clinical studies; (2) the funding of research programs; (3) the discovery, testing, and approval of new treatments, and (4) the training of clinical scientists. Rigorous, statistically-valid, natural history-controlled, cross-over, and n-of-1 trials can establish efficacy and support regulatory approval of new treatments for rare diseases. The U.S. Orphan Drug Act of the U.S. FDA has stimulated industry investment in clinical trials to develop treatments for rare diseases. For trainees interested in finding a treatment for a rare disease, a commitment to longitudinal care of patients provides a base for the characterization of phenotype and natural history, a stimulus for innovation, a target population for research and helps fund training and research. The scientific methodology, financial resources, and logistics of clinical research for rare diseases have changed dramatically in the past two decades resulting in increased understanding of the pathophysiology of these disorders and direct benefit to patients.

Integrating Neglected Tropical Diseases into AIDS, Tuberculosis, and Malaria Control

Peter J. Hotez, M.D., Ph.D., Neeraj Mistry, M.D., M.P.H., Joanna Rubinstein, D.D.S., Ph.D., and Jeffrey D. Sachs, Ph.D.

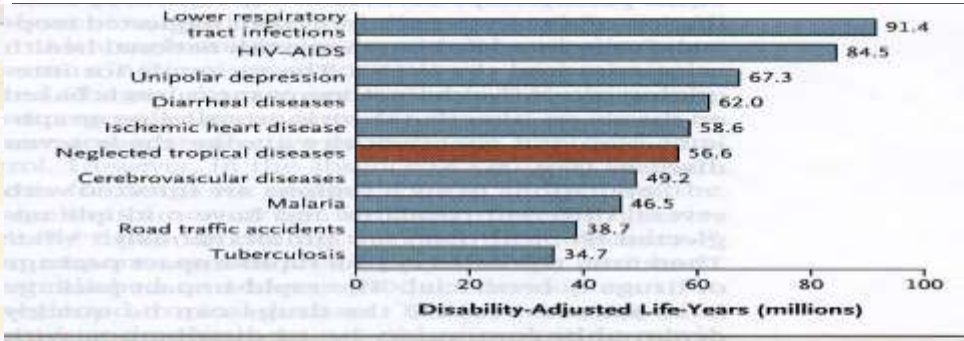

Figure 1. The 10 Leading Causes of Life-Years Lost to Disability and Premature Death.

The number of years lost to disability and premature death (disability-adjusted life-years) for the 13 major neglected tropical diseases were calculated according to a method we described previously.[4] The disability-adjusted life-years for the other conditions are based on data from the World Health Organization.[23] The ranking of disease burdens is based on data in Hotez.[5]

Figure 2. Nations with Five, Six, or Seven Neglected Tropical Diseases to Be Targeted for Integrated Preventive Chemotherapy.

Of the 56 nations to be targeted with a rapid-impact package, shown in yellow, 37 are located in the World Health Organization (WHO) African region, 5 in the WHO Region of the Americas, 5 in the WHO Eastern Mediterranean region, 3 in the WHO South-East Asia region, and 6 in the WHO Western Pacific region. Data regarding the occurrence of lymphatic filariasis, onchocerciasis, schistosomiasis, and the three soil-transmitted helminth infections are derived from the WHO.[44] Data regarding the occurrence of trachoma are derived from the WHO.[45] The five nations shown in orange — Burkina Faso, Ghana, Mali, Niger, and Uganda — will be targeted for integrated control in national programs through the support of the U.S. Agency for International Development Neglected Tropical Disease Control Program beginning this year. The two nations shown in red — Rwanda and Burundi — will be targeted for integrated control in national programs through the support of Geneva Global beginning this year.

Population Age Shifts Reshape Global Economics and Geopolitics

Adele Hayutin, Ph.D.
Director, Global Aging Program
Stanford Center on Longevity
ahayutin@stanford.edu

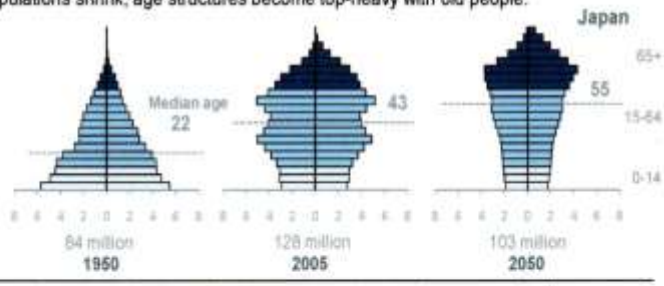
Populations Shift to Older People: Pyramid to Cube

As fertility falls and longevity increases, a country's age profile changes from a pyramid with a broad base of young people to a cube with a more even distribution across age brackets. If fertility remains low, the population will become top-heavy with older people.

The share of older people (65+) is increasing almost everywhere, but at different rates depending on changes in fertility and longevity. These population age shifts have profound impacts on everything from a country's workforce growth and economic prospects to public and personal budgets, security risks, cultural institutions and family structures.

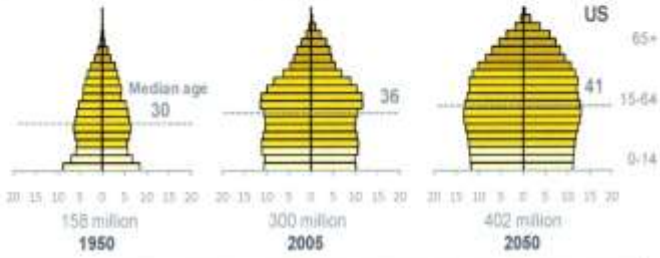
Oldest Countries: Working-age populations shrink; age structures become top-heavy with old people.

- Fertility has been below replacement level of 2.1 births per woman for the last 10-15 years.
- Working-age population (15-64) is shrinking.
- Declining workforce growth combined with the increasing fiscal burden of retirees threatens economic growth and current living standards.
- Selected countries: *Germany, Italy, Japan, Singapore, South Korea, Spain.*



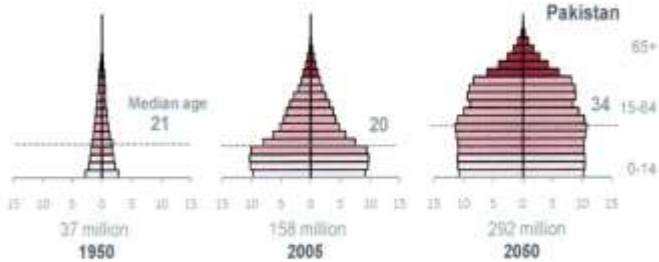
Middle-Age Countries: Workforce growth continues but at a slower pace; age structures become cube-like.

- Fertility rates are approaching or already below replacement rate.
- Workforce growth will be slow or moderate, eventually becoming negative in some countries.
- Sustained economic growth will require productivity gains to offset slower workforce growth.
- Selected countries: *Australia, Brazil, Canada, China, Ireland, Mexico, Thailand, Tunisia, United States, Vietnam.*



Young Countries: Rapid growth in working-age population threatens economic and political stability.

- Fertility rates are falling but still relatively high; age structure remains pyramidal.
- Working-age population will continue to grow rapidly, though the pace will slow.
- "Youth bulges" increase the risk of violent conflict; the challenge is to provide work for a large share of young adults.
- Selected countries: *Afghanistan, Bolivia, Nigeria, India, Iraq, Pakistan, Philippines, Uganda.*



Population in millions by five-year age bracket. Males on left, females on right.

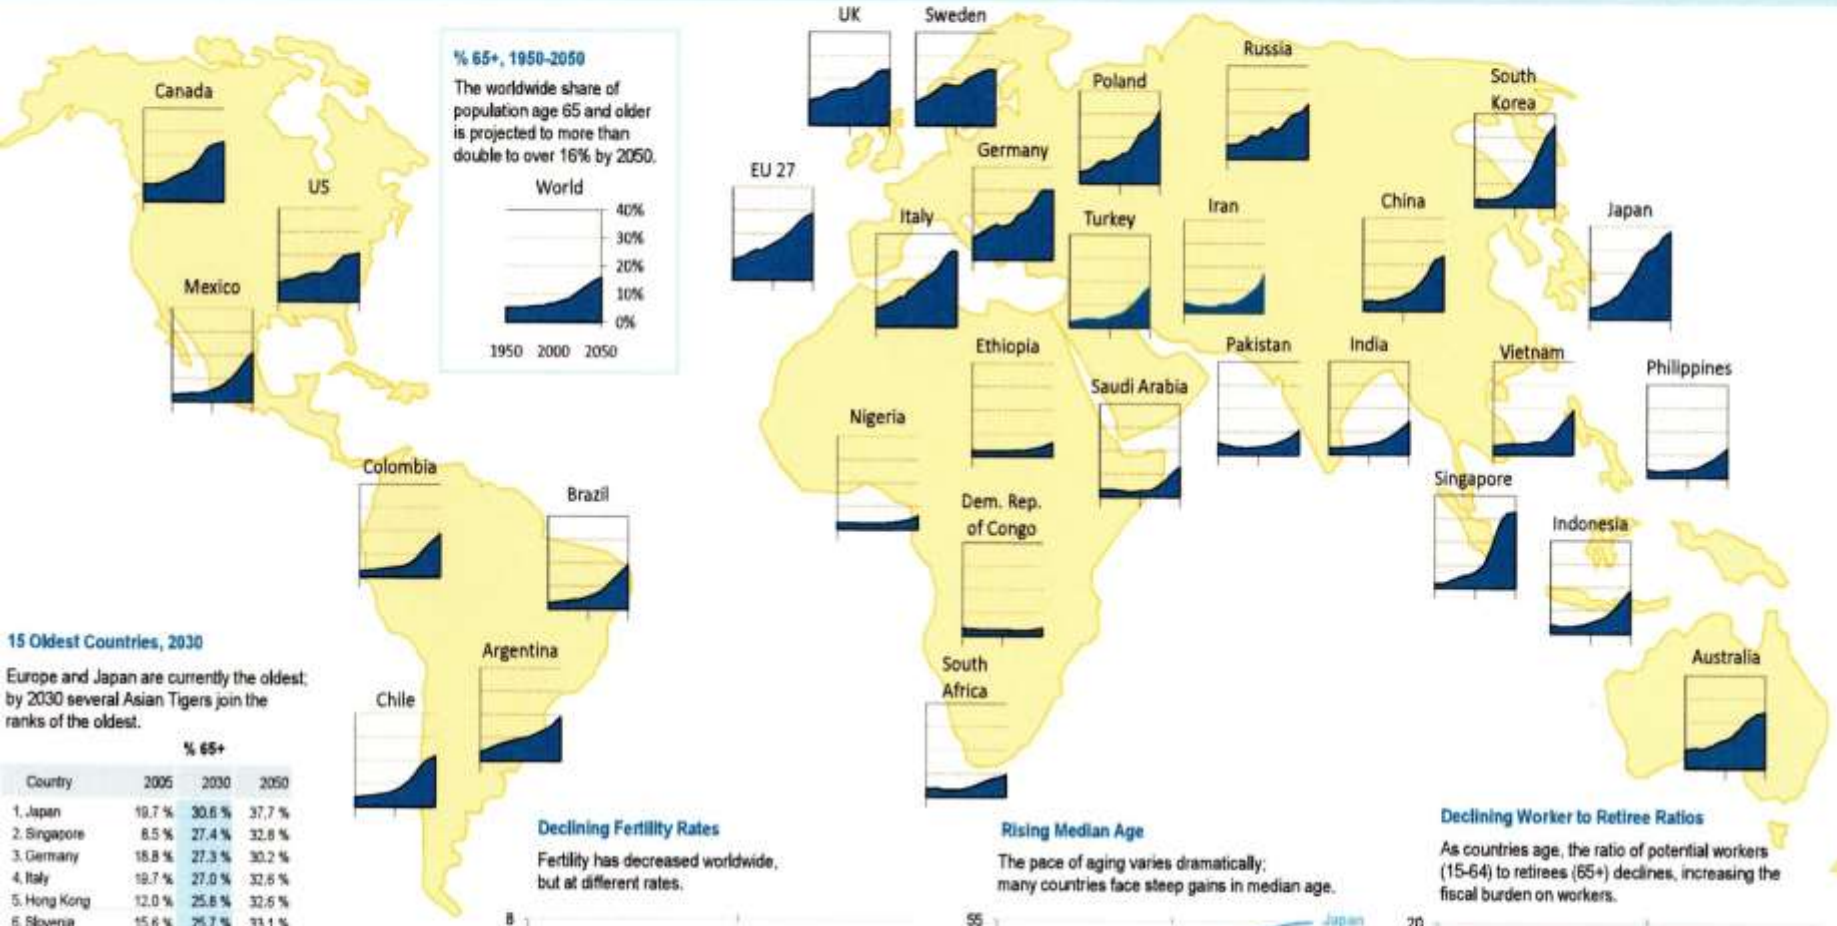
Global Aging

Share of Population Age 65 and Older

Dramatic and unprecedented population age shifts are occurring at vastly different rates around the world.



% 65+, 1950-2050

The worldwide share of population age 65 and older is projected to more than double to over 16% by 2050.

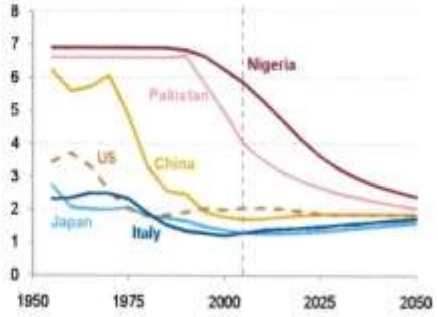
15 Oldest Countries, 2030

Europe and Japan are currently the oldest; by 2030 several Asian Tigers join the ranks of the oldest.

	% 65+		
Country	2005	2030	2050
1. Japan	19.7 %	30.6 %	37.7 %
2. Singapore	8.5 %	27.4 %	32.8 %
3. Germany	18.8 %	27.3 %	30.2 %
4. Italy	19.7 %	27.0 %	32.6 %
5. Hong Kong	12.0 %	25.8 %	32.6 %
6. Slovenia	15.6 %	25.7 %	33.1 %
7. Finland	15.9 %	25.0 %	25.6 %
8. Austria	16.2 %	24.6 %	29.0 %
9. Belgium	17.3 %	24.4 %	27.1 %
10. Greece	18.3 %	24.2 %	31.7 %
11. Netherlands	14.2 %	24.1 %	25.2 %
12. Croatia	17.2 %	24.1 %	28.5 %
13. Spain	16.8 %	23.9 %	33.2 %
14. Switzerland	15.4 %	23.9 %	25.0 %
15. South Korea	9.4 %	23.4 %	35.1 %
US	12.3 %	19.4 %	21.0 %
EU 27	16.7 %	23.9 %	28.7 %
World	7.3 %	11.7 %	16.2 %

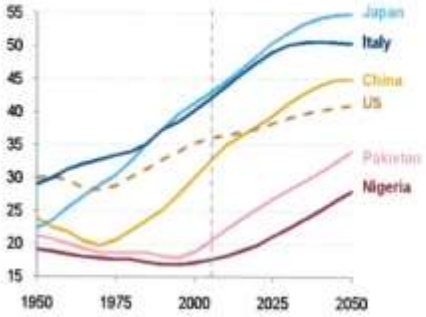
Declining Fertility Rates

Fertility has decreased worldwide, but at different rates.



Rising Median Age

The pace of aging varies dramatically; many countries face steep gains in median age.



Declining Worker to Retiree Ratios

As countries age, the ratio of potential workers (15-64) to retirees (65+) declines, increasing the fiscal burden on workers.

Preventing CHRONIC DISEASES a vital investment

World Health Organization

PART ONE: OVERVIEW

CHRONIC DISEASES ARE THE MAJOR CAUSE OF DEATH IN ALMOST ALL COUNTRIES

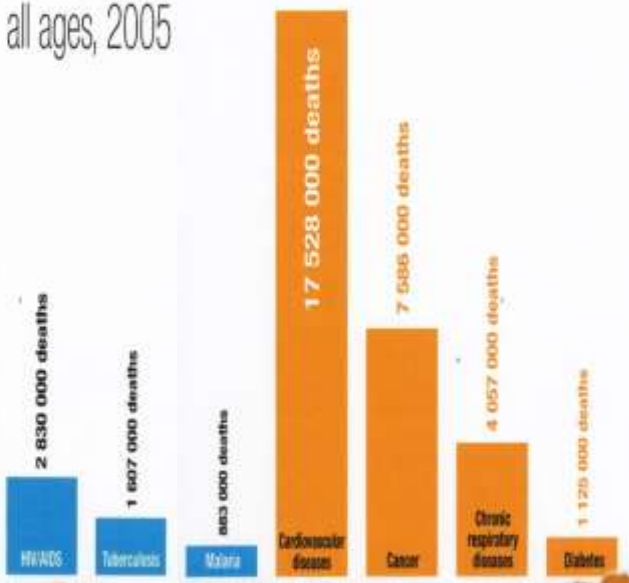
Chronic diseases include heart disease, stroke, cancer, chronic respiratory diseases and diabetes. Visual impairment and blindness, hearing impairment and deafness, oral diseases and genetic disorders are other chronic conditions that account for a substantial portion of the global burden of disease.

From a projected total of 58 million deaths from all causes in 2005,[1] it is estimated that chronic diseases will account for 35 million, which is double the number of deaths from all infectious diseases (including HIV/AIDS, tuberculosis and malaria), maternal and perinatal conditions, and nutritional deficiencies combined.

[1] The data presented in this overview were estimated by WHO using standard methods to maximize cross-country comparability. They are not necessarily the official statistics of Member States.

35 000 000 people will die from chronic diseases in 2005

Projected global deaths by cause, all ages, 2005



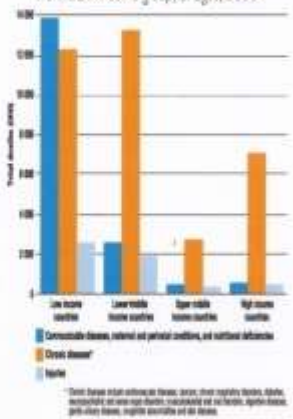
60% of all deaths are due to chronic diseases

PART ONE: OVERVIEW

THE POOREST COUNTRIES ARE THE WORST AFFECTED

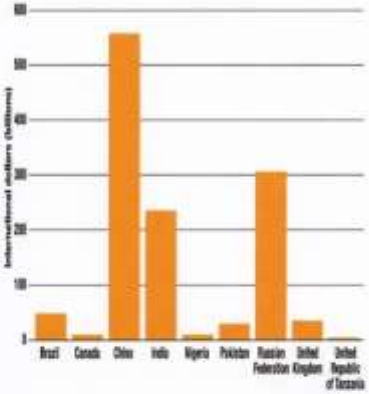
Only 20% of chronic disease deaths occur in high income countries – while 80% occur in low and middle income countries, where most of the world's population lives. As this report will show, even least developed countries such as the United Republic of Tanzania are not immune to the growing problem.

Projected deaths by major cause and World Bank income group, all ages, 2005



80% of chronic disease deaths occur in low and middle income countries

Projected foregone national income due to heart disease, stroke and diabetes in selected countries, 2005–2015



THE PROBLEM HAS SERIOUS IMPACT

The burden of chronic disease:

- has major adverse effects on the quality of life of affected individuals;
- causes premature death;
- creates large adverse – and underappreciated – economic effects on families, communities and societies in general.

$558 billion

The estimated amount China will forego in national income over the next 10 years as a result of premature deaths caused by heart disease, stroke and diabetes

CHRONIC DISEASE

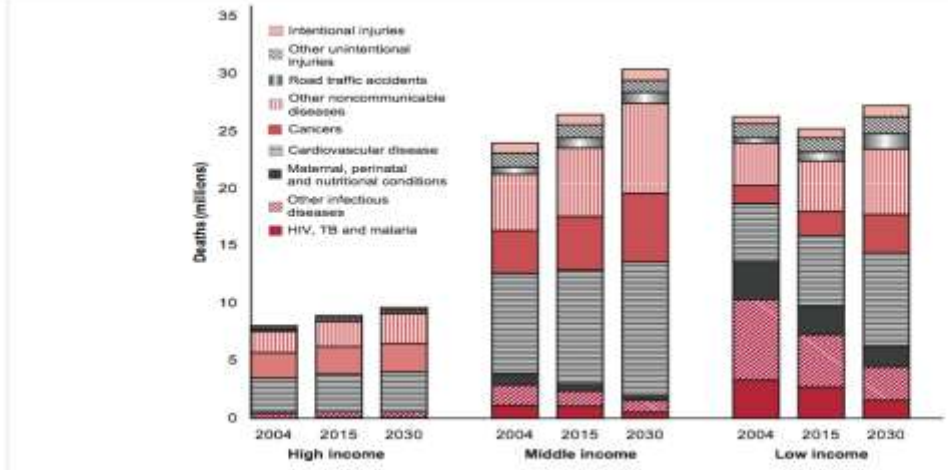
PROJECTED DEATHS BY CAUSE FOR HIGH-, MIDDLE- AND LOW-INCOME COUNTRIES



Chronic Diseases 1

The burden and costs of chronic diseases in low-income and middle-income countries

Dele O Abegunde, Colin D Mathers, Taghreed Adam, Monica Ortegon, Kathleen Strong

This paper estimates the disease burden and loss of economic output associated with chronic diseases—mainly cardiovascular diseases, cancer, chronic respiratory diseases, and diabetes—in 23 selected countries which account for around 80% of the total burden of chronic disease mortality in developing countries. In these 23 selected low-income and middle-income countries, chronic diseases were responsible for 50% of the total disease burden in 2005. For 15 of the selected countries where death registration data are available, the estimated age-standardised death rates for chronic diseases in 2005 were 54% higher for men and 86% higher for women than those for men and women in high-income countries. If nothing is done to reduce the risk of chronic diseases, an estimated US$84 billion of economic production will be lost from heart disease, stroke, and diabetes alone in these 23 countries between 2006 and 2015. Achievement of a global goal for chronic disease prevention and control—an additional 2% yearly reduction in chronic disease death rates over the next 10 years—would avert 24 million deaths in these countries, and would save an estimated $8 billion, which is almost 10% of the projected loss in national income over the next 10 years.

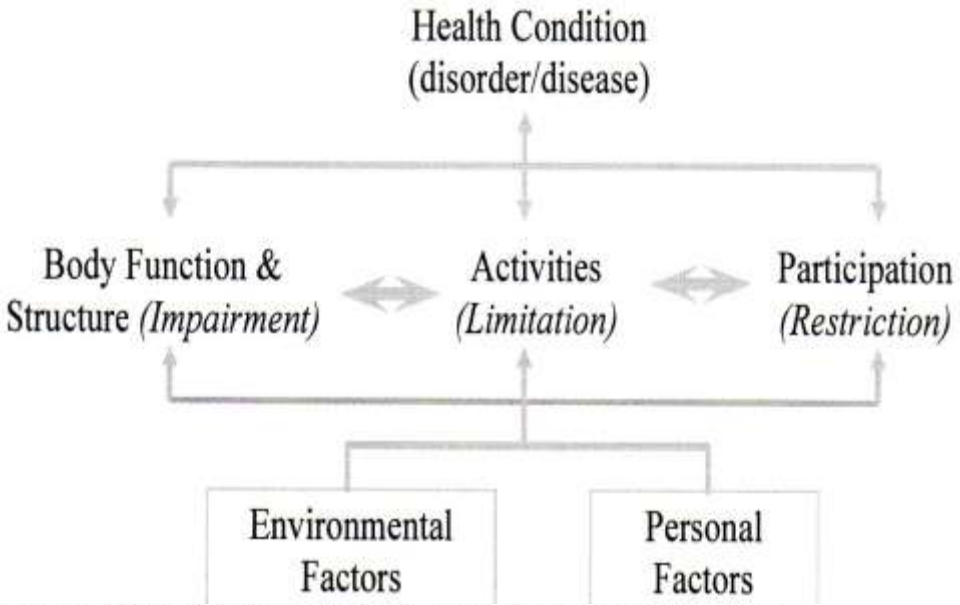
Measuring Disability Prevalence

Daniel Mont

March 2007

Social Protection
THE WORLD BANK

Figure 1: The ICF Model



Box 1: WHO-Disability Assessment Schedule -- 12-Question Set

In the last 30 days how much difficulty did you have in:
(None Mild Moderate Severe Extreme Cannot Do)

Standing for long periods such as 30 minutes?

Taking care of your household responsibilities?

Learning a new task, for example, learning how to get to a new place?

How much of a problem did you have joining in community activities (for example, festivities, religious or other activities) in the same way as anyone else can?

How much have you been emotionally affected by your health problems?

Concentrating on doing something for ten minutes?

Walking a long distance such as a kilometre [or equivalent]?

Washing your whole body?

Getting dressed?

Dealing with people you do not know?

Maintaining a friendship?

Your day to day work?

Current and future worldwide prevalence of dependency, its relationship to total population, and dependency ratios

Rowan H. Harwood,[1] Avan Aihie Sayer,[2] & Miriam Hirschfeld[3]

Objective To estimate the number of people worldwide requiring daily assistance from another person in carrying out health, domestic or personal tasks.
Methods Data from the Global Burden of Disease Study were used to calculate the prevalence of severe levels of disability, and consequently, to estimate dependency. Population projections were used to forecast changes over the next 50 years.
Findings The greatest burden of dependency currently falls in sub-Saharan Africa, where the "dependency ratio" (ratio of dependent people to the population of working age) is about 10%, compared with 7–8% elsewhere. Large increases in prevalence are predicted in sub-Saharan Africa, the Middle East, Asia and Latin America of up to 5-fold or 6-fold in some cases. These increases will occur in the context of generally increasing populations, and dependency ratios will increase modestly to about 10%. The dependency ratio will increase more in China (14%) and India (12%) than in other areas with large prevalence increases. Established market economies, especially Europe and Japan, will experience modest increases in the prevalence of dependency (30%), and in the dependency ratio (up to 10%). Former Socialist economies of Europe will have static or declining numbers of dependent people, but will have large increases in the dependency ratio (up to 13%).
Conclusion Many countries will be greatly affected by the increasing number of dependent people and will need to identify the human and financial resources to support them. Much improved collection of data on disability and on the needs of caregivers is required. The prevention of disability and provision of support for caregivers needs greater priority.

Claire E. Sharda, RN, MBA
Ronald J. Ozminkowski, PhD
Sean Nicholson, PhD
Gary M. Billotti, MS
Robin S. Turpin, PhD
Michael Olson, PhD
Marc L. Berger, MD

Objective: *The objective of this study was to determine the prevalence and estimate total costs for chronic health conditions in the U.S. workforce for the Dow Chemical Company (Dow).* ***Methods:*** *Using the Stanford Presenteeism Scale, information was collected from workers at five locations on work impairment and absenteeism based on self-reported "primary" chronic health conditions. Survey data were merged with employee demographics, medical and pharmaceutical claims, smoking status, biometric health risk factors, payroll records, and job type.* ***Results:*** *Almost 65% of respondents reported having one or more of the surveyed chronic conditions. The most common were allergies, arthritis/joint pain or stiffness, and back or neck disorders. The associated absenteeism by chronic condition ranged from 0.9 to 5.9 hours in a 4-week period, and on-the-job work impairment ranged from a 17.8% to 36.4% decrement in ability to function at work. The presence of a chronic condition was the most important determinant of the reported levels of work impairment and absence after adjusting for other factors (P < 0.000). The total cost of chronic conditions was estimated to be 10.7% of the total labor costs for Dow in the United States; 6.8% was attributable to work impairment alone.* ***Conclusion:*** *For all chronic conditions studied, the cost associated with performance based work loss or "presenteeism" greatly exceeded the combined costs of absenteeism and medical treatment combined.* (J Occup Environ Med. 2005;47:547–557)

Les grandes étapes de la recherche

Par Marine Benoiste, avec la collaboration de Jérôme Pierrel, historien des sciences au laboratoire Épistémé de l'université Bordeaux-I

DU MICROBE ENNEMI AU MICROBE ALLIÉ

►1878
Le médecin Charles Sédillot crée le terme de « microbe » pour nommer l'ensemble des organismes vivants invisibles à l'œil nu. Plus tard, ils seront qualifiés de micro-organismes.

►1880
Les Français Louis Pasteur, Charles Chamberland et Émile Roux, développent un vaccin contre le choléra des poules, à l'aide de cultures du microbe (lire « Principes de mort et principes de vie », p. 64).

►1882
Le médecin allemand Robert Koch pense identifier le bacille de la tuberculose. Pour confirmer sa découverte, il le met en culture et l'utilise pour reproduire la maladie chez des animaux.

►1884
Robert Koch et le bactériologiste allemand Friedrich Löffler définissent les critères pour établir un lien de cause à effet entre un micro-organisme et une maladie.

►1885
En injectant de la moelle épinière de lapin atteint de la rage à un enfant victime de morsures par un chien enragé, Pasteur prévient tout développement de la maladie. C'est le premier vaccin contre la rage.

►1892
Après filtration de la sève de feuilles atteintes de la mosaïque du tabac, le Russe Dmitri I. Ivanovski montre que l'agent responsable de cette maladie végétale est trop petit pour être une bactérie.

►1898
Le botaniste néerlandais Martinus W. Beijerinck attribue la maladie de la mosaïque du tabac à un agent infectieux « vivant » et « fluide ». Pour désigner ce dernier, il emploie le terme « virus ».

►1907
Elie Metchnikoff, immunologiste russe, étudie les bactéries produisant le lait fermenté : il suggère que ces bactéries sont bénéfiques pour la santé humaine.

ALEXANDER FLEMING a isolé la pénicilline à partir du champignon *Penicillium notatum*. Le biologiste écossais reçut le prix Nobel en 1945 pour cette découverte de ce qui allait être le premier antibiotique.

►1915
L'Anglais Frederick Twort découvre des virus qui infectent spécifiquement les bactéries.

►1917
Le Français Félix d'Hérelle les redécouvre et les nomme « bactériophages » (lire « Des virus pour lutter contre les bactéries », p. 42).

►1928
Une substance antibactérienne produite par des moisissures *Penicillium notatum* est isolée inopinément par le biologiste écossais Alexander Fleming. C'est la pénicilline.

►1939
Grâce à l'un des premiers microscopes électroniques, Gustav-Adolf Kausche, Edgar Pfankuch et Helmut Ruska visualisent l'agent de la mosaïque du tabac. C'est le premier virus observé.

►1944
La société pharmaceutique américaine Pfizer inaugure la première usine de production de pénicilline. Les soldats alliés disposent de cet antibiotique lors du Débarquement en Normandie.

►1972
Le biochimiste américain Paul Berg et ses collègues construisent un ADN constitué d'ADN bactérien et d'ADN viral : c'est le premier ADN recombinant (lire « La peur conjurée du génie génétique », p. 60).

LE MÉDECIN ALAIN FISCHER et ses collègues de l'hôpital Necker ont utilisé avec succès la thérapie génique en 2000 pour traiter des nourrissons atteints de déficit immunitaire combiné sévère. Ces enfants étaient auparavant contraints de vivre sous une bulle stérile.

►1973
Les Américains Stanley Cohen et Herbert Boyer insèrent un ADN recombinant portant des gènes de résistance à des antibiotiques dans une bactérie *Escherichia coli*. C'est le premier organisme génétiquement modifié.

►1978
La compagnie pharmaceutique Genentech, fondée par Herbert Boyer et Robert Swanson, transfère le gène de l'insuline humaine dans une bactérie. C'est l'une des premières fabrications d'hormone par un organisme transformé génétiquement.

►1982
L'agence américaine de sécurité sanitaire, la FDA, donne son feu vert à la commercialisation d'insuline produite par génie génétique. Il s'agit du premier médicament ainsi fabriqué industriellement (lire « Des mini-usines à médicaments », p. 46).

►2000
Alain Fischer et Marina Cavazzana-Calvo, médecins à l'hôpital Necker à Paris, annoncent que deux nourrissons ont été traités avec succès par thérapie génique : une première (lire « Comment on corrige des gènes », p. 46).

►2006
Jeffrey Gordon et ses collaborateurs de l'université Washington, à Saint Louis, aux États-Unis, montrent que le microbiote intestinal (auparavant appelé « flore intestinale ») joue un rôle dans l'obésité (lire « Des bactéries qui stockent des graisses », p. 28).

►2010
Les premiers résultats du projet MetaHIT, mis en place pour caractériser génétiquement le microbiote intestinal humain, sont publiés. 3,3 millions de gènes bactériens ont été identifiés (lire « Un autre génome pour l'homme », p. 22).

REVIEW ARTICLE

Resistance to Antibiotics: Are We in the Post-Antibiotic Era?

Alfonso J. Alanis

Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, Indiana

Received for publication June 11, 2005; accepted June 23, 2005 (ARCMED-D-05-00223).

Serious infections caused by bacteria that have become resistant to commonly used antibiotics have become a major global healthcare problem in the 21st century. They not only are more severe and require longer and more complex treatments, but they are also significantly more expensive to diagnose and to treat. Antibiotic resistance, initially a problem of the hospital setting associated with an increased number of hospital-acquired infections usually in critically ill and immunosuppressed patients, has now extended into the community causing severe infections difficult to diagnose and treat. The molecular mechanisms by which bacteria have become resistant to antibiotics are diverse and complex. Bacteria have developed resistance to all different classes of antibiotics discovered to date. The most frequent type of resistance is acquired and transmitted horizontally via the conjugation of a plasmid. In recent times new mechanisms of resistance have resulted in the simultaneous development of resistance to several antibiotic classes creating very dangerous multidrug-resistant (MDR) bacterial strains, some also known as "superbugs". The indiscriminate and inappropriate use of antibiotics in outpatient clinics, hospitalized patients and in the food industry is the single largest factor leading to antibiotic resistance. In recent years, the number of new antibiotics licensed for human use in different parts of the world has been lower than in the recent past. In addition, there has been less innovation in the field of antimicrobial discovery research and development. The pharmaceutical industry, large academic institutions or the government are not investing the necessary resources to produce the next generation of newer safe and effective antimicrobial drugs. In many cases, large pharmaceutical companies have terminated their anti-infective research programs altogether due to economic reasons. The potential negative consequences of all these events are relevant because they put society at risk for the spread of potentially serious MDR bacterial infections.

Key Words: Antibiotic resistance, Bacterial resistance, New antibiotics, Antibiotic research.

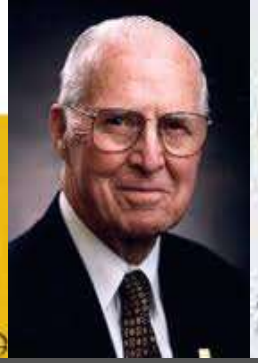
AN ESSAY on the PRINCIPLE OF POPULATION;

HUMAN HAPPINESS;

By T. R. MALTHUS, A. M.

IN TWO VOLUMES.

VOL. I.



- " … o crescimento populacional vai inevitavelmente tornar insuficiente a capacidade mundial de produção alimentar, razão pela qual irá imperar futuramente a fome e a miséria … " (sic.) (Thomas Malthus, 1803)
- " … calcula-se que entre 30 a 40 % do total de alimentos sejam desperdiçados … " (FAO Report, 2004)
- " … calcula-se que cerca de 20 % das emissões de gases nocivos para a atmosfera (designadamente metano e oxido nítrico), resultam das actividades relacionadas directa ou indirectamente com a agricultura … " (sic.) (H. Charles J. Godfrey, et al, 2010)

Phil. Trans. R. Soc. B (2010) 365, 2769–2777
doi:10.1098/rstb.2010.0180

Introduction

The future of the global food system

H. Charles J. Godfray[1,*], Ian R. Crute[2], Lawrence Haddad[3], David Lawrence[4], James F. Muir[5], Nicholas Nisbett[6], Jules Pretty[7], Sherman Robinson[8], Camilla Toulmin[9] and Rosalind Whiteley[9]

- " … nós não seremos capazes de alimentar todos os habitantes do mundo até ao final do presente milénio utilizando apenas os actuais meios tecnológicos e práticas. Insistir nessa falsa ideia de que isso será possível, só condenará milhões de pessoas à condição de famintos, bem como produzirá o caos social, económico e político … " (sic.) (Norman Borlaug)
- " … a prática actual da agricultura tem sido dominada por um discurso centrado nas questões tecnológicas, ignorando aspectos muito mais importantes de natureza económica e social, e negligenciado outros domínios do conhecimento, designadamente o saber tradicional e a experiência acumulada das populações. O resultado desta postura materializou-se na imposição inadequada de modelos de desenvolvimento menos consentâneos, de que a biotecnologia é uma das suas últimas variantes … " (sic.) (Miguel Altieri e Peter Rosset)

Em 2100, seremos um planeta de dez mil milhões de pessoas

Europa será o único continente a ver a sua população decrescer nos próximos 90 anos

De 2004 para cá, o índice dos preços da comida da FAO mais do que duplicou, enquanto os preços do petróleo foram de uns modestos 40 dólares o barril em 2000 para um pico de quase 140 em 2008. Os biocombustíveis estão a desviar comida da boca das pessoas para os depósitos automóveis. A água escasseia. O planeta está a consumir por ano, segundo a ONG World Wide Fund, 50% mais do que a terra consegue suportar. **É neste cenário que vamos bater mais um recorde de crescimento populacional**

UM FUTURO SEM 'SOL VERDE'

A bomba demográfica há muito tempo temida não chegará a explodir. Segundo as mais recentes projeções da ONU, a população mundial deverá estabilizar em redor dos nove mil milhões de habitantes, no ano 2050. Ao mesmo tempo, a produção agrícola e, logo, a ração diária disponível, deverá aumentar. Produzir comida suficiente para satisfazer as necessidades da população tornar-se-á possível, mas não sem ameaçar gravemente outros recursos, nomeadamente a água.

SABOR
EXÓTICO

E para comer, quer cobra, canguru ou girafa?

Os portugueses passaram a ter à mesa novos sabores, exóticos e desconhecidos. Fomos provar onze tipos de carne 'estranha', do kudu à zebra, passando pela cobra, girafa ou canguru. E contamos a história de produtos alimentares nacionais. TEXTOS DE **KATYA DELIMBEUF**

alimentação | europa

Insetos procuram um lugar no menu dos europeus

Desde 2008 que a FAO (Organização das Nações Unidas para a Agricultura e Alimentação) recomenda o consumo de insetos ao invés da carne, por motivos tanto económicos como ecológicos. Mas na Europa, a mensagem não é bem recebida e as iniciativas nesse sentido são marginais.

IF SMALLPOX STRIKES PORTLAND ...

BY CHRIS L. BARRETT, STEPHEN G. EUBANK AND JAMES P. SMITH

"EPISIMS" UNLEASHES VIRTUAL PLAGUES IN REAL CITIES TO SEE HOW SOCIAL NETWORKS SPREAD DISEASE. THAT KNOWLEDGE MIGHT HELP STOP EPIDEMICS

CREATING THE EPISIMS

The original EpiSims model was based on Portland, Ore., but gathering sufficiently detailed information about 1.6 million real people and their activities would have been difficult and intrusive. A synthetic population, statistically indistinguishable from the real one, could nonetheless be constructed and given realistic daily lives using publicly available data.

SYNTHETIC HOUSEHOLDS

The U.S. Census Bureau provided demographic information, such as age, household composition and income, for the entire city as well as 5 percent of its complete records for smaller study areas of a few square blocks. Through a statistical technique called iterative proportional fitting, these two data sets were combined to create households and individuals with statistically correct demographics and geographic distribution.

ACTIVITIES

Most metropolitan planning offices conduct detailed traveler activity surveys for small population samples of a few thousand. These logs track the movements of each household member over the course of one or more days, noting the time of each activity. By matching the demographics of survey respondents to the entire synthetic population, realistic daily activities can be generated for every synthetic household member.

LOCATIONS

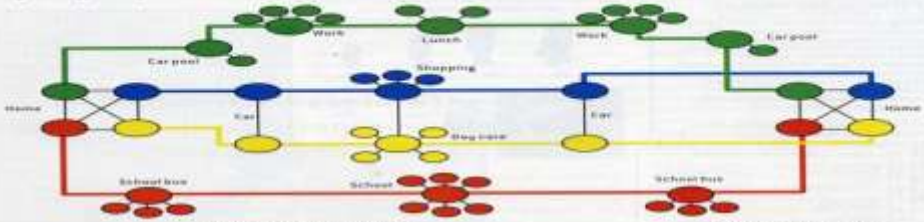
Setting the population in motion requires assigning locations to every household's activities. Land-use data for buildings, parking lots, parks and other places were associated with 180,000 locations in the model, providing estimates of the number of people performing various types of activities there. Activities were anchored to individuals' work or school locations, and then places were chosen for additional activities, such as grocery shopping or recreation, taking into account their distance and other measures of their appeal.

BUILDING SOCIAL NETWORKS

TYPICAL HOUSEHOLD'S CONTACTS

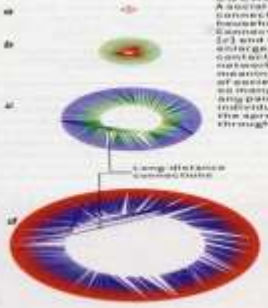
Constructing a social network for a household of two adults and two children starts by identifying their contacts with other people throughout a typical day.

This diagram shows where the household members go and what they do all day but reveals little about how their individual contacts might be interconnected or connected to others.



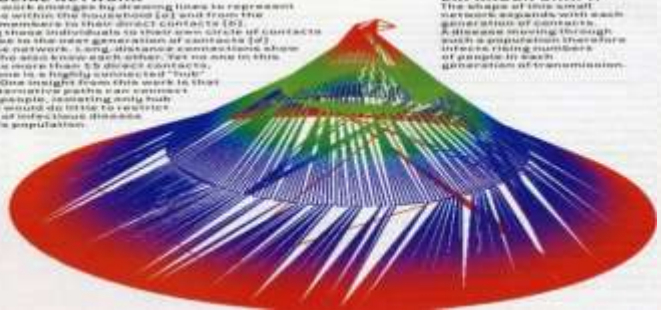
LOCAL SOCIAL NETWORK

A social network emerges by drawing lines to represent connections within the household (a) and from the household members to their direct contacts (b). Connecting these individuals to their own circle of contacts (c) and those to the next generation of contacts (d) enlarges the network. Long-distance connections show contacts who also know each other. Yet no one in this network has more than 55 direct contacts, meaning there is a highly connected "hub" of society. One insight from this work is that so many alternative paths can connect any pair of people, rendering only bulk interventions would do little to restrict the spread of infectious disease through this population.



EXPANDER GRAPH

The shape of this small network expands with each generation of contacts. A disease moving through such a population therefore incurs rising numbers of people in each generation of transmission.



SIMULATED SMALLPOX ATTACKS

EpiSims animations depict simulated outbreaks and the effects of official interventions. In the still frames below, vertical lines indicate the number of infected people present at a location, and color shows the percentage of them who are contagious. In both scenarios shown, smallpox is released at a university in central Portland, but the attack is not detected until victims start experiencing symptoms 10 days later. The left-hand images show no public health response as a baseline. In the right-hand images, infected and exposed individuals are targeted for vaccination and quarantine. Results from a series of such simulations (bottom) show that people who stay in their homes early in an outbreak makes the biggest difference in death toll. The speed of official response, regardless of the strategy chosen, proved to be the second most important factor.

DAY 1: UNDETECTED SMALLPOX RELEASE

NO RESPONSE

INFECTED: 1,281
DEAD: 0

TARGETED VACCINATION AND QUARANTINE STARTING DAY 14

INFECTED: 1,281
QUARANTINED: 0
VACCINATED: 0
DEAD: 0

DAY 35: SMALLPOX EPIDEMIC

INFECTED: 23,918
DEAD: 331

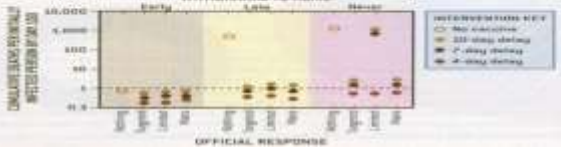
INFECTED: 2,564
QUARANTINED: 29,910
VACCINATED: 30,560
DEAD: 312

DAY 70: EPIDEMIC UNCONTAINED OR CONTAINED

INFECTED: 390,582
DEAD: 12,488

INFECTED: 2,564
QUARANTINED: 96,725
VACCINATED: 37,207
DEAD: 495

WITHDRAWAL TO HOME



RESPONSE EFFECTIVENESS

Simulations allowed people to withdraw to their homes because they felt ill or were following officials' instructions. Withdrawal could be "early," before anyone became contagious, or "never," meaning people continued mixing even once they died. "Late" withdrawal, 24 hours after becoming contagious, was less effective than early withdrawal, which prevented an epidemic without other intervention. Official responses included doing nothing, or targeted vaccination and quarantine with unlimited personnel, or targeted vaccination limited by only half the necessary personnel being available, or mass vaccination of the entire population. The interventions began four, seven or 10 days after the first victims became symptomatic.

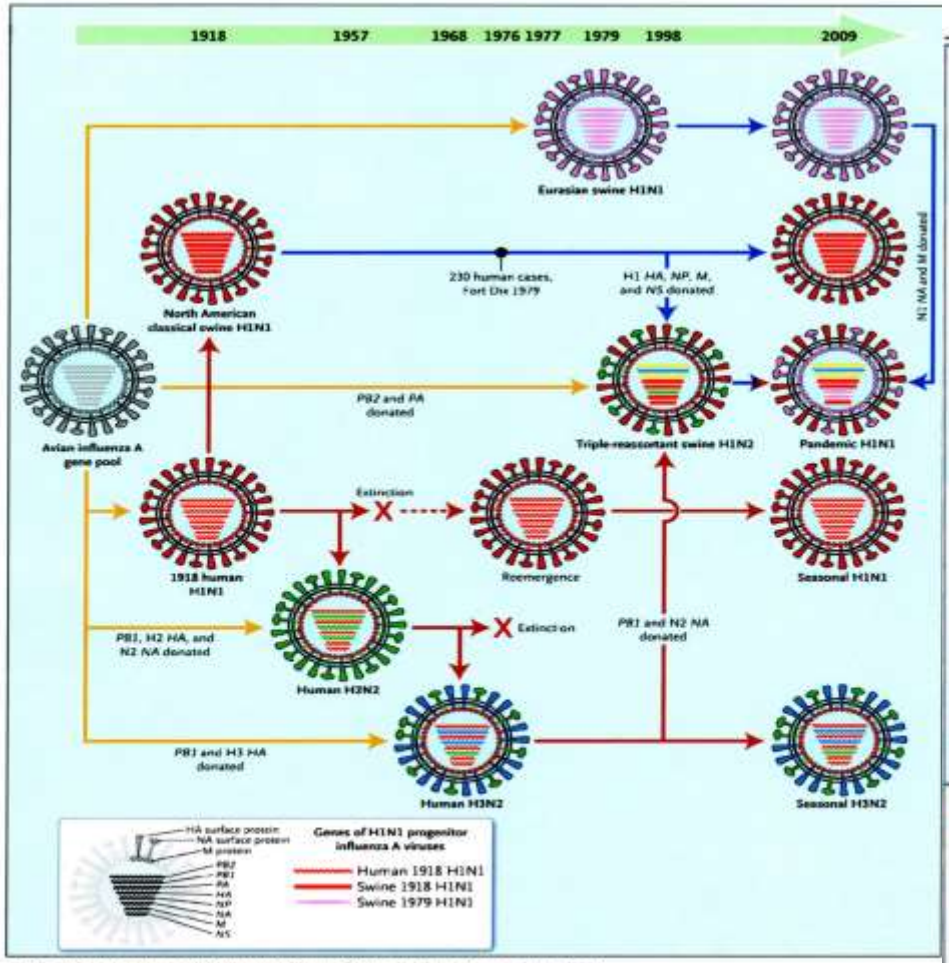
Historical Perspective — Emergence of Influenza A (H1N1) Viruses

Shanta M. Zimmer, M.D., and Donald S. Burke, M.D.

The NEW ENGLAND JOURNAL of MEDICINE



Genetic Relationships among Human and Relevant Swine Influenza Viruses, 1918–2009.

Yellow arrows reflect exportation of one or more genes from the avian influenza A virus gene pool. The dashed red arrow indicates a period without circulation. Solid red arrows indicate the evolutionary paths of human influenza virus lineages; solid blue arrows, of swine influenza virus lineages; and the blue-to-red arrow, of a swine-origin human influenza virus. All influenza A viruses contain eight genes that encode the following proteins (shown from top to bottom within each virus): polymerase PB2, polymerase PB1, polymerase PA, hemagglutinin (HA), nuclear protein (NP), neuraminidase (NA), matrix proteins (M), and nonstructural proteins (NS). The genes of the 1918 human and swine H1N1 and the 1979 H1N1 influenza A viruses were all recently descended from avian influenza A genes, and some have been "donated" to the pandemic human H1N1 strain.

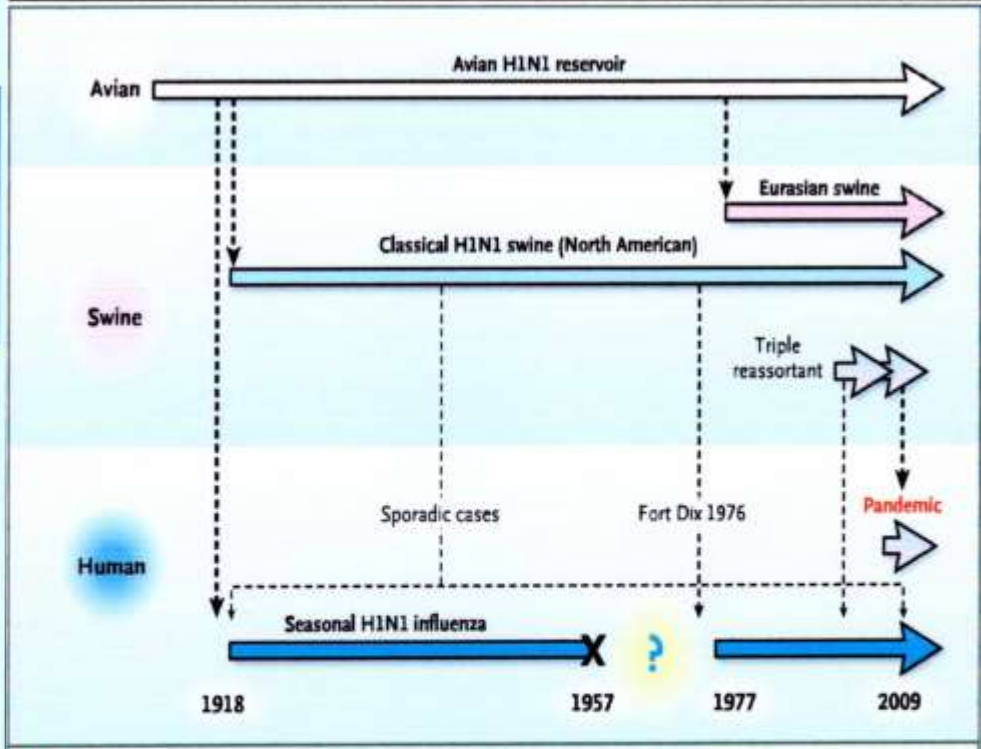


Figure 1. Emergence of Influenza A (H1N1) Viruses from Birds and Swine into Humans.

The diagram shows the important events and processes in the emergence of influenza A (H1N1) viruses during the past 91 years. Avian, swine, and human populations are represented in the top, middle, and bottom of the diagram, respectively. Epidemic or zoonotic viruses are shown as wide horizontal arrows (white for avian viruses, light blue or pink for swine viruses, and dark blue for human viruses). Cross-species transmissions are shown as vertical dashed lines, with thick lines for transfers that gave rise to sustained transmission in the new host and thin lines for those that were transient and resulted in a self-limited number of cases. Principal dates are shown along the bottom of the diagram. The disappearance of H1N1 in 1957 most likely represents competition by the emerging pandemic H2N2 strain in the face of population immunity to H1N1. The reemergence in 1977 is unexplained and probably represents reintroduction to humans from a laboratory source.

INHIBITORS

Inhibitors compete with other drugs for a particular enzyme thus affecting the optimal level of metabolism of the substrate drug which in many cases affect the individual's response to that particular medication, e.g. making it ineffective.

strong — A **Strong inhibitor** is one that cause a > 5-fold increase in the plasma AUC values or more than 80% decrease in clearance.

moderate — A **Moderate inhibitor** is one that cause a > 2-fold increase in the plasma AUC values or 50-80% decrease in clearance.

weak — A **Weak inhibitor** is one that cause a > 1.25-fold but < 2-fold increase in the plasma AUC values or 20-50% decrease in clearance.

others — All other inhibitors.

FDA preferred[1] and acceptable[2] **inhibitors** for in vitro experiments.*

INDUCERS

Inducers stimulate the production of the enzyme thus increasing the rate of metabolism causing the substrate drug to clear out of the system faster. This will also affect the individual's response to the medication, i.e. making he drug ineffective because it has not been in the system long enough to have an effect.

Edited by John M. Coffin, Tufts University School of Medicine, Boston, MA, and approved February 13, 2007 (received for review January 17, 2007)

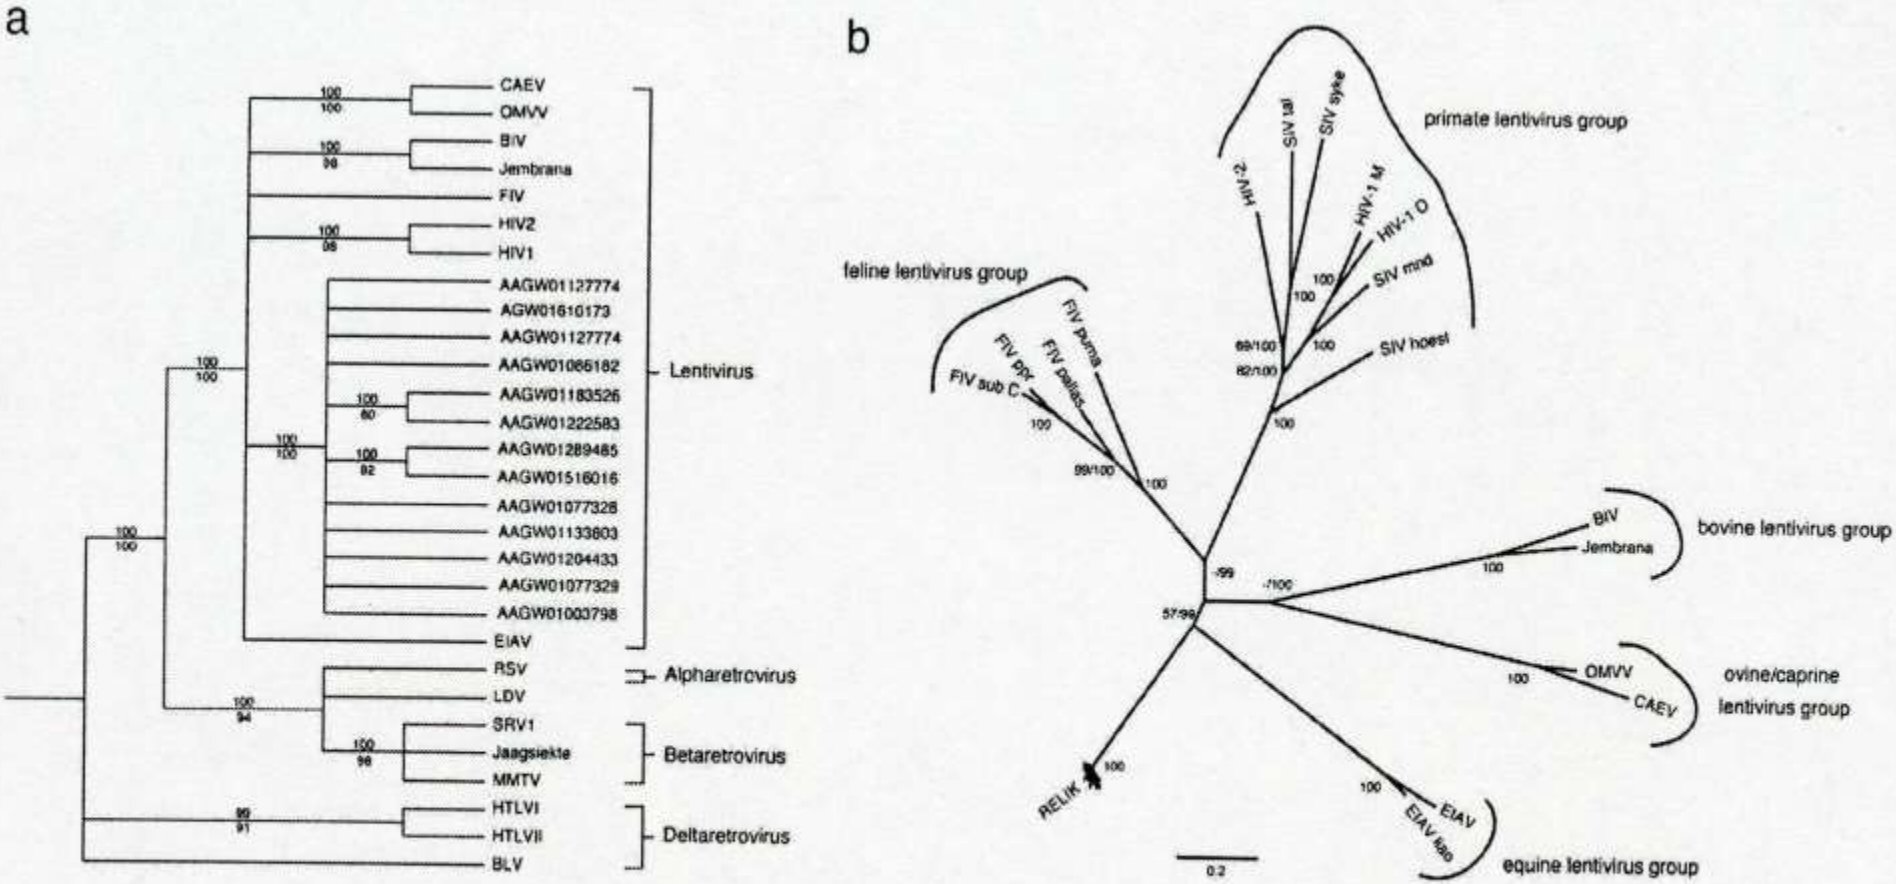

Fig. 3. Phylogenetic relationships of RELIK to other retroviruses. (*a*) Phylogeny of RELIK and other lentiviruses together with a sample of nonlentiviral exogenous retroviruses, rooted on BLV, HTLV1, and HTLV2. Support for the ML trees was assessed via 1,000 nonparametric bootstrap replicates, and posterior clade probabilities were assessed for the Bayesian phylogeny. Both support indices are indicated as values out of 100, with posterior clade probabilities indicated above the branches and bootstrap scores below. Branches with posterior probabilities <95% were collapsed. The RELIK sequences are indicated by their accession numbers. (*b*) Unrooted phylogeny showing the relationships of the lentiviruses. Bootstrap scores and Bayesian posterior probabilities are indicated to the left and right of the forward slash, respectively, and nodes with only 100 indicated showed maximal support under both measures.

Towards a conceptual framework to support one-health research for policy on emerging zoonoses

Richard Coker, Jonathan Rushton, Sandra Mounier-Jack, Esron Karimuribo, Pascal Lutumba, Dominic Kambarage, Dirk U Pfeiffer, Katharina Stärk, Mark Rweyemamu

In the past two decades there has been a growing realisation that the livestock sector was in a process of change, resulting from an expansion of intensive animal production systems and trade to meet a globalised world's increasing demand for livestock products. One unintended consequence has been the emergence and spread of transboundary animal diseases and, more specifically, the resurgence and emergence of zoonotic diseases. Concurrent with changes in the livestock sector, contact with wildlife has increased. This development has increased the risk of transmission of infections from wildlife to human beings and livestock. Two overarching questions arise with respect to the real and perceived threat from emerging infectious diseases: why are these problems arising with increasing frequency, and how should we manage and control them? A clear conceptual research framework can provide a guide to ensure a research strategy that coherently links to the overarching goals of policy makers. We propose such a new framework in support of a research and policy-generation strategy to help to address the challenges posed by emerging zoonoses.

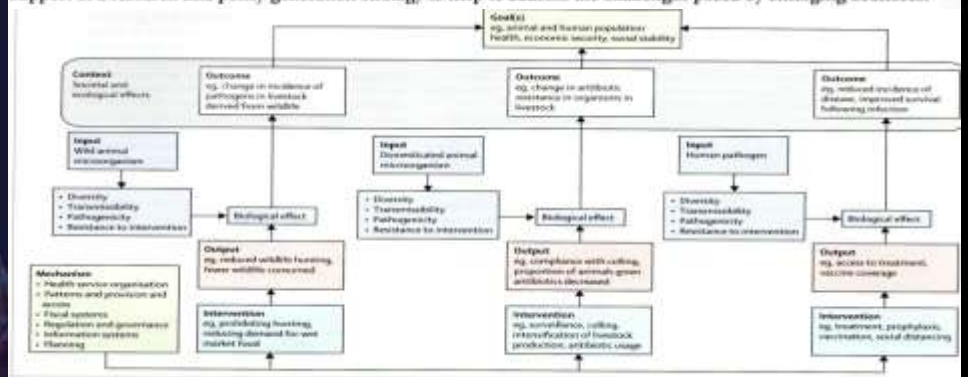

Figure: Schematic representation of a framework for research to inform one-health policy

Probable Zoonotic Leprosy in the Southern United States

Richard W. Truman, Ph.D., Pushpendra Singh, Ph.D., Rahul Sharma, Ph.D., Philippe Busso, Jacques Rougemont, Ph.D., Alberto Paniz-Mondolfi, M.D., Adamandia Kapopoulou, M.S., Sylvain Brisse, Ph.D., David M. Scollard, M.D., Ph.D., Thomas P. Gillis, Ph.D., and Stewart T. Cole, Ph.D.

ABSTRACT

BACKGROUND

In the southern region of the United States, such as in Louisiana and Texas, there are autochthonous cases of leprosy among native-born Americans with no history of foreign exposure. In the same region, as well as in Mexico, wild armadillos are infected with *Mycobacterium leprae*.

METHODS

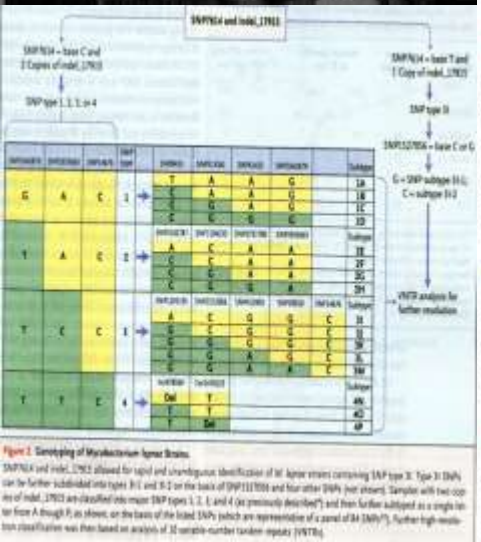
Whole-genome resequencing of *M. leprae* from one wild armadillo and three U.S. patients with leprosy revealed that the infective strains were essentially identical. Comparative genomic analysis of these strains and *M. leprae* strains from Asia and Brazil identified 51 single-nucleotide polymorphisms and an 11-bp insertion–deletion. We genotyped these polymorphic sites, in combination with 10 variable-number tandem repeats, in *M. leprae* strains obtained from 33 wild armadillos from five southern states, 50 U.S. outpatients seen at a clinic in Louisiana, and 64 Venezuelan patients, as well as in four foreign reference strains.

RESULTS

The *M. leprae* genotype of patients with foreign exposure generally reflected their country of origin or travel history. However, a unique *M. leprae* genotype (3I-2-v1) was found in 28 of the 33 wild armadillos and 25 of the 39 U.S. patients who resided in areas where exposure to armadillo-borne *M. leprae* was possible. This genotype has not been reported elsewhere in the world.

CONCLUSIONS

Wild armadillos and many patients with leprosy in the southern United States are infected with the same strain of *M. leprae*. Armadillos are a large natural reservoir for *M. leprae*, and leprosy may be a zoonosis in the region. (Funded by the National Institute of Allergy and Infectious Diseases and others.)



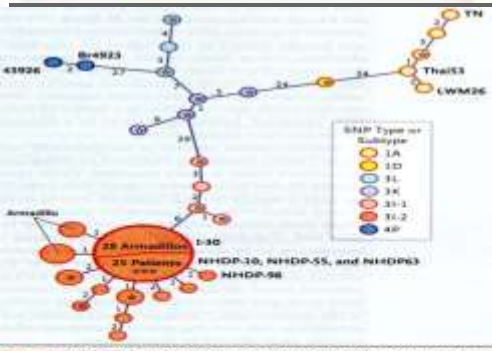


Figure 1. Minimum-Spanning Phylogenetic Tree of *Mycobacterium leprae* Genotypes Based on Analysis of Single-Nucleotide Polymorphisms (SNPs) and Variable-Number Tandem Repeats (VNTRs).

Minimum-spanning-tree analysis was performed with the use of combined VNTR and SNP data from human and armadillo *M. leprae* strains. Each circle represents a genotype (human unless marked as armadillo) based on the combined data, with the circle size directly proportional to the number of strains with the corresponding genotype. Numbers along the links between circles indicate the number of loci that differ between the genotypes on either side of the link. Three fully sequenced reference *M. leprae* strains (TN, Thai53, and Br4923[13,29]) are labeled, as are two other reference strains (LWM26 and 43926) of foreign origin. Samples from patients with a history of foreign residence are indicated with an asterisk (with three asterisks indicating three patients). The 114 polymorphisms investigated include 84 SNPs described previously[29] and 30 identified during our study. 10 VNTRs were also analyzed. The large circle illustrates the predominance of the 3I-2-v1 *M. leprae* genotype in our study, with 25 patients and 28 armadillos having this identical genotype.

Ex Vivo Gene Therapy
copies of therapeutic gene
gene inserted into viral DNA
target cells removed from patient
cells grown in culture
cultured cells are infected with genetically-altered virus
patient's sample target cells are now genetically altered with therapeutic gene
cells are reintroduced into body
Ex vivo gene therapy is performed with the genetic alterations of patient's target cells happening outside of the body in a culture. Target cells from the patient are infected with a recombinant virus containing the desired therapeutic gene. These modified cells are then reintroduced into the patient's body, where they produce the needed proteins that correspond to the inserted gene.
Inside the body, the genetically altered cells produce the desired proteins encoded by the therapeutic DNA

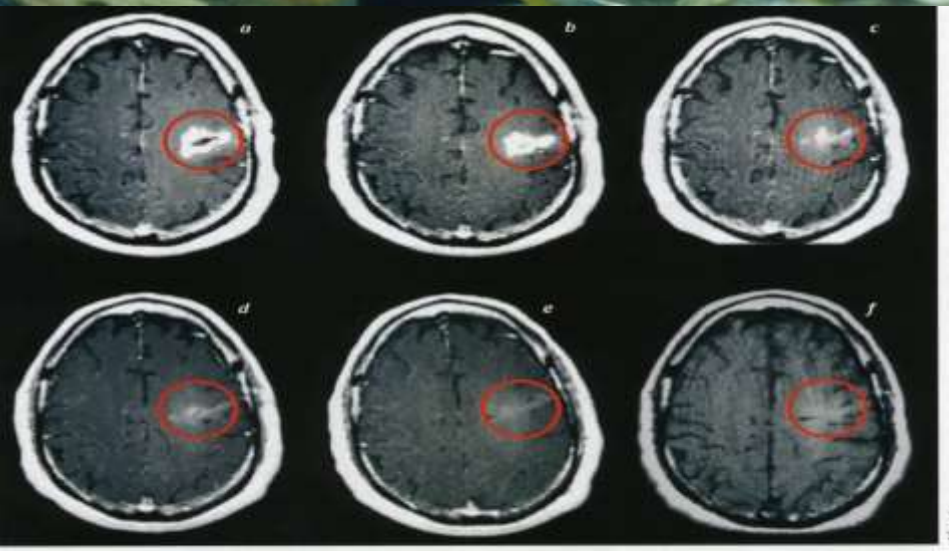
Des cancers
traités par des virus

J. ROMMELAERE, C. DINSART, A. RÉGNIER-VIGOUROUX, N. SALOMÉ, J. SCHLEHOFER

Les traitements conventionnels contre les cancers ont une efficacité limitée dans de nombreux cas. La thérapie oncolytique, fondée sur l'utilisation de virus tueurs de tumeurs, offre de nouvelles perspectives dans la lutte contre ce fléau mondial.

1. CETTE BULLE STERILE protégeait David, atteint d'un déficit immunitaire combiné sévère (DICS), maladie héréditaire. Un essai de thérapie génique, réalisé en 1999 à l'Hôpital Necker de Paris, a permis de soigner huit enfants. Par la suite, des améliorations des vecteurs rétroviraux ont été proposées.

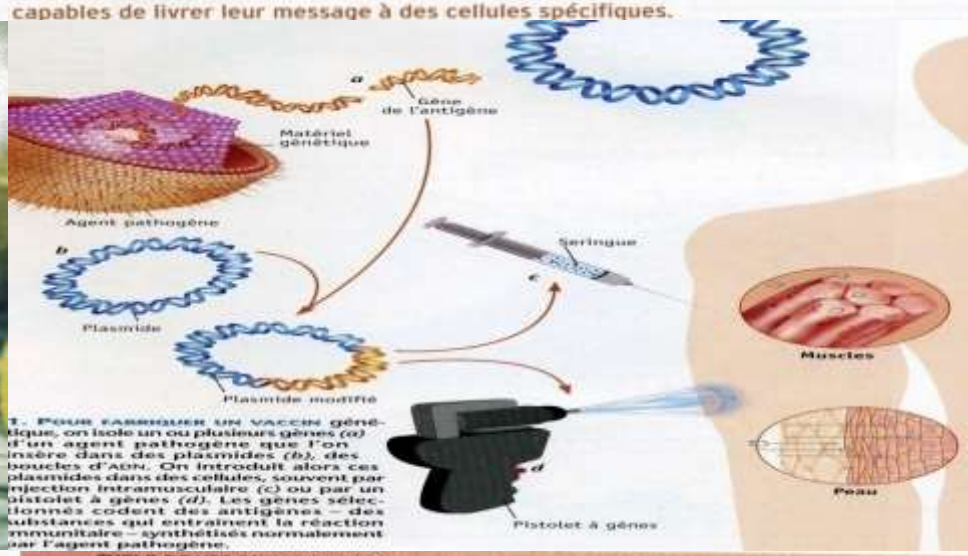


3. RÉGRESSION D'UNE TUMEUR CÉRÉBRALE. Des essais cliniques ont montré l'efficacité de la thérapie oncolytique sur des cellules gliales cancéreuses du cerveau. L'injection de virus de la maladie de Newcastle a provoqué la régression de la tumeur *(de a à f)*, comme le montrent les images par résonance magnétique prises lors du test, en 2006.

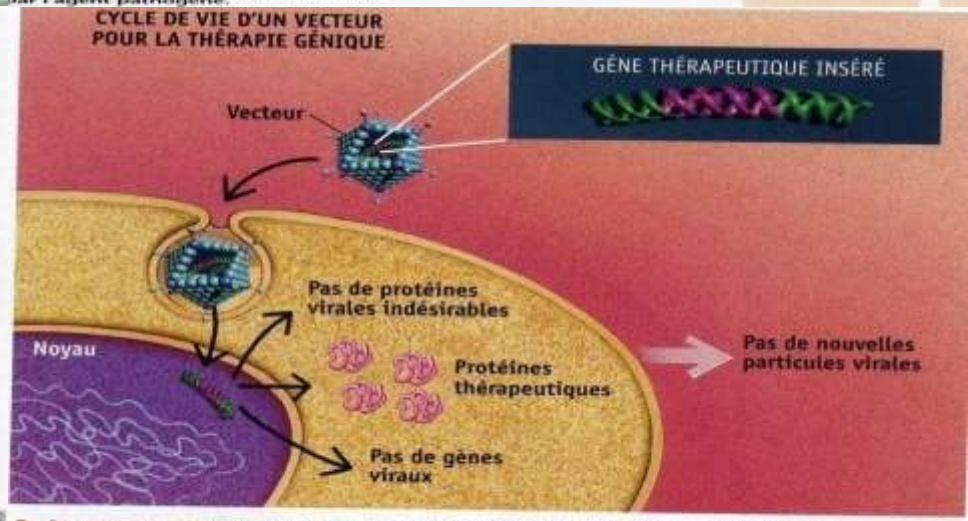
Les virus vecteurs
de molécules thérapeutiques

Jean-Christophe PAGÈS et Éric PIVER

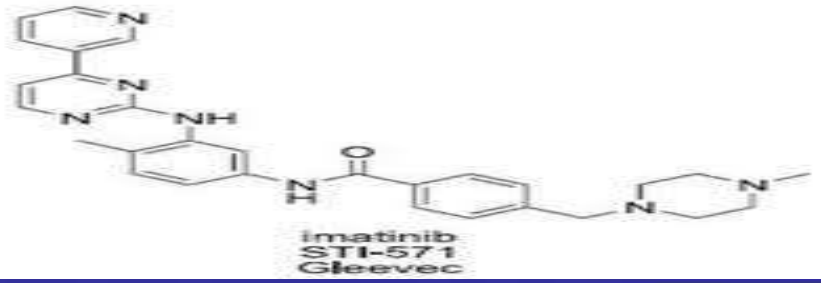
En désamorçant leur pouvoir pathogène, on convertit des virus en vecteurs d'instructions génétiques. Ceux-ci deviennent des outils thérapeutiques, capables de livrer leur message à des cellules spécifiques.

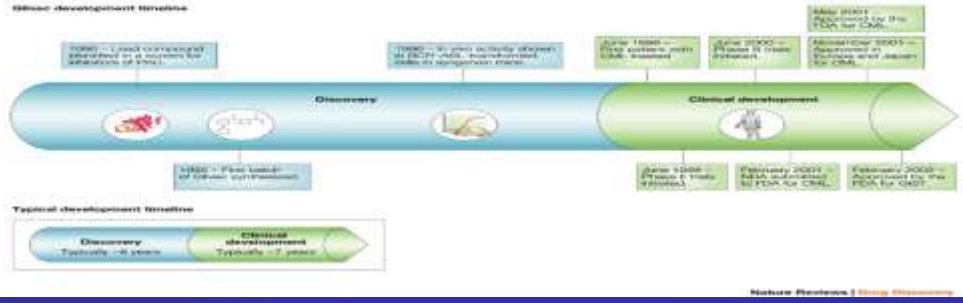


1. POUR FABRIQUER UN VACCIN génétique, on isole un ou plusieurs gènes *(a)* d'un agent pathogène que l'on insère dans des plasmides *(b)*, des boucles d'ADN. On introduit alors ces plasmides dans des cellules, souvent par injection intramusculaire *(c)* ou par un pistolet à gènes *(d)*. Les gènes sélectionnés codent des antigènes – des substances qui entraînent la réaction immunitaire – synthétisés normalement par l'agent pathogène.

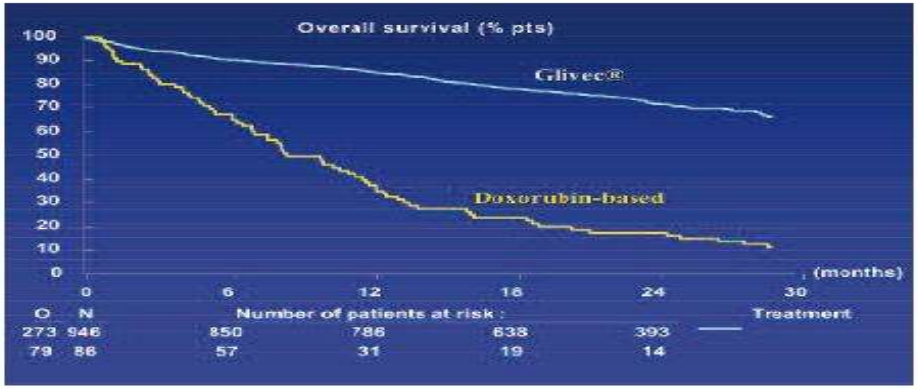


3. LE CYCLE D'UN VECTEUR VIRAL est tronqué par rapport à celui d'un virus : ne sont conservés que l'entrée et le transfert nucléaire du génome, qui permettront l'expression du gène thérapeutique. Comme les gènes structuraux ne sont plus présents dans le génome du vecteur, celui-ci est incapable de se multiplier.





IMATINIB GREATLY IMPROVED SURVIVAL IN GIST



Results from the Conticanet series of GIST patients demonstrated the huge survival benefit conferred by the new therapy

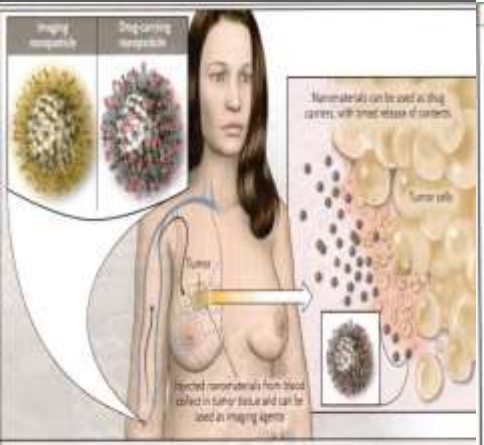

Figure 3. Nanomaterials Used as Drug Carriers or Contrast Agents for In Vivo Cancer Applications.

Tumors have poor lymphatic drainage, and their vessels are highly porous. This enables nanomaterials to diffuse and accumulate in the tumor matrix. Nanomaterials that carry chemotherapeutic agents can target and kill tumor cells, whereas nanomaterials that are magnetic or fluorescent are used as imaging agents for detecting tumors.

Table 1. Examples of Nanomaterials in Clinical Use.*

Nanovaccines: recent developments in vaccination

TARALA D NANDEDKAR
National Institute for Research in Reproductive Health, Indian Council for Medical Research, Parel, Mumbai 400 012, India
(Fax, +91 22 2413 94 12; Email, nandedkartarala@yahoo.co.in)

In the past 100 years, vaccination has contributed immensely to public health by preventing a number of infectious diseases. Attenuated, killed or part of the microorganism is employed to stimulate the immune system against it. Progress in biotechnology has provided protective immunity through DNA vaccines. In recent years, nanovaccine is a novel approach to the methodology of vaccination. Nanomaterials are delivered in the form of microspheres, nano-beads or micro-nanoprojections. Painless, effective and safe needle-free routes such as the intranasal or the oral route, or patches of microprojections to the skin are some of the approaches which are in the experimental stage at present but may have a great future ahead in nanovaccination.

Point-of-Care Diagnostics for Infectious Diseases: DxBox

Health need

While fever is a common symptom of illness, clinicians often cannot distinguish between bacterial, parasitic, viral, fungal, or noninfectious causes. In the absence of an accurate diagnostic that identifies the causative agent of a fever, treatment is based on regional prevalence of infections. In sub-Saharan Africa, fever is often treated with antimalarial drugs, which leads to over-prescription and mismanagement of the patient's care regimen. The emergence of antimalarial and antibiotic drug resistance results in an urgent need for accurate diagnosis of fever-causing agents at point-of-care in resource-limited settings.

Prototype of the DxBox instrument with a disposable device.

Abstract and Introduction

Abstract

Extrapolation from recent disease history suggests that changes in the global environment, including virus, vector and human behavior, will continue to influence the spectrum of viruses to which humans are exposed. In this article, these environmental changes will be enumerated, and their potential impact on target-focused, nucleic acid-based diagnostic tests will be considered, followed by a presentation of some emerging technological responses.

Table 1. The overlapping spectrum of possible signs and symptoms for some of the clinically significant flaviviruses.

Virus	Symptom							
	Fever	*Headache*	*Nausea/vomiting*	*Dizziness/disorientation*	*Encephalitis*	*Myalgia*	*Rash*	*Hemorrhagic fever*
MVEV	√	√	√	√	√	√	√	
YFV	√	√	√	√	√	√	√ Jaundice	√
DENV	√	√	√	√	√	√	√ Jaundice	√
WNV	√	√	√	√	√	√	√	
JEV	√	√	√	√	√			
KUNV	√	√	√	√	Rare	√		
USUV	√	√	√	√		√		
TBEV	√	√	√	√	√	√		
SLEV	√	√	√	√	√	√		
KFDV	√	√	√	√	√	√		√
OHFV	√	√	√	√	√	√	√	√
AHFV	√	√	√	√	√	√		√

Not all symptoms or signs occur in all cases and there are febrile or meningoencephalitic forms of some of the diseases (e.g., TBEV), which present and progress differently. For several of these viruses, a significant proportion of infections can be asymptomatic (e.g., WNV). Substantial fatality is associated with symptomatic JEV, MVEV, AKHV, KFDV, WNV, DENV and YFV in unvaccinated populations.

AHFV: Alkhurma hemorrhagic fever virus; DENV: Dengue virus; JEV: Japanese encephalitis virus; KFDV: Kyasanur Forest disease virus; KUNV: Kunjin virus; MVEV: Murray Valley encephalitis; OHFV: Omsk hemorrhagic fever virus; SLEV: St Louis encephalitis virus; TBEV: Tick-borne encephalitis virus; USUV: Usutu virus; WNV: West Nile virus; YFV: Yellow fever virus.

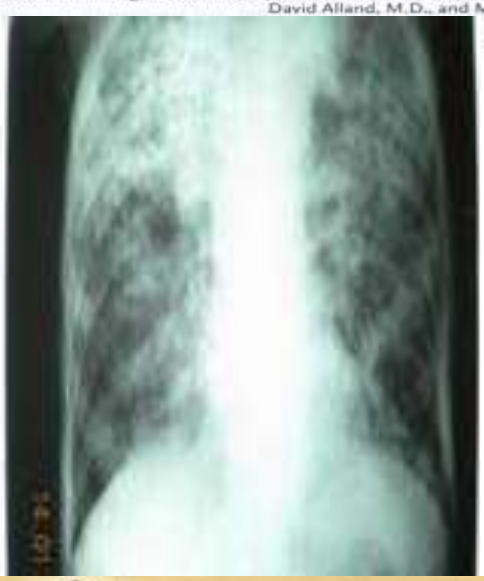

Figure 9.

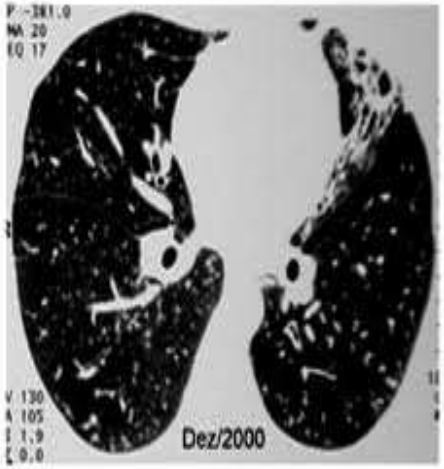

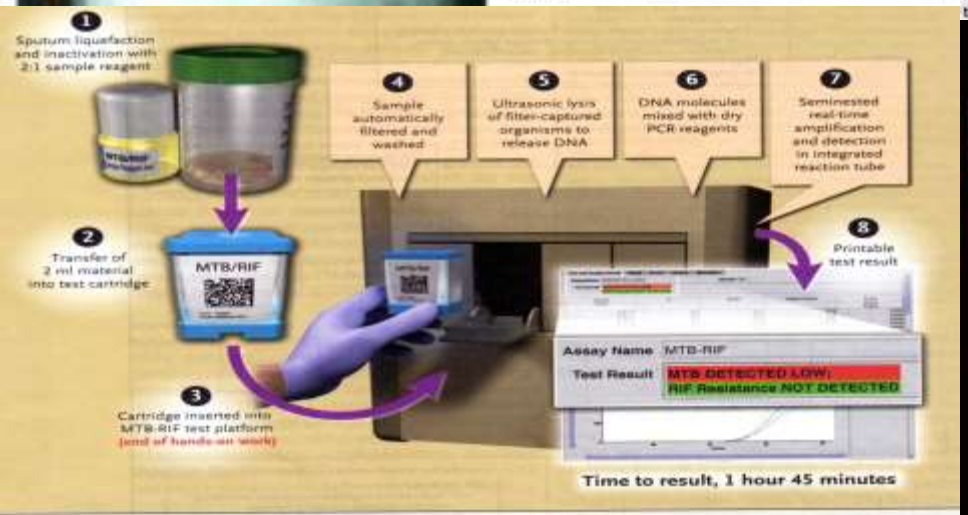

Figure 2. **Assay Procedure for the MTB/RIF Test.**
Two volumes of sample treatment reagent are added to each volume of sputum. The mixture is shaken, incubated at room temperature for 15 minutes, and shaken again. Next, a sample of 2 to 3 ml is transferred to the test cartridge, which is then loaded into the instrument. All subsequent steps occur automatically. The user is provided with a printable test result, such as "MTB detected; RIF resistance not detected." PCR denotes polymerase chain reaction.

GENOMICS

Hepatitis C virus gets personal

Shawn P. Iadonato and Michael G. Katze

Many people infected with the hepatitis C virus are not cured despite gruelling therapy. A human genetic variant that predicts successful treatment has been identified. So is personalized therapy now a possibility?

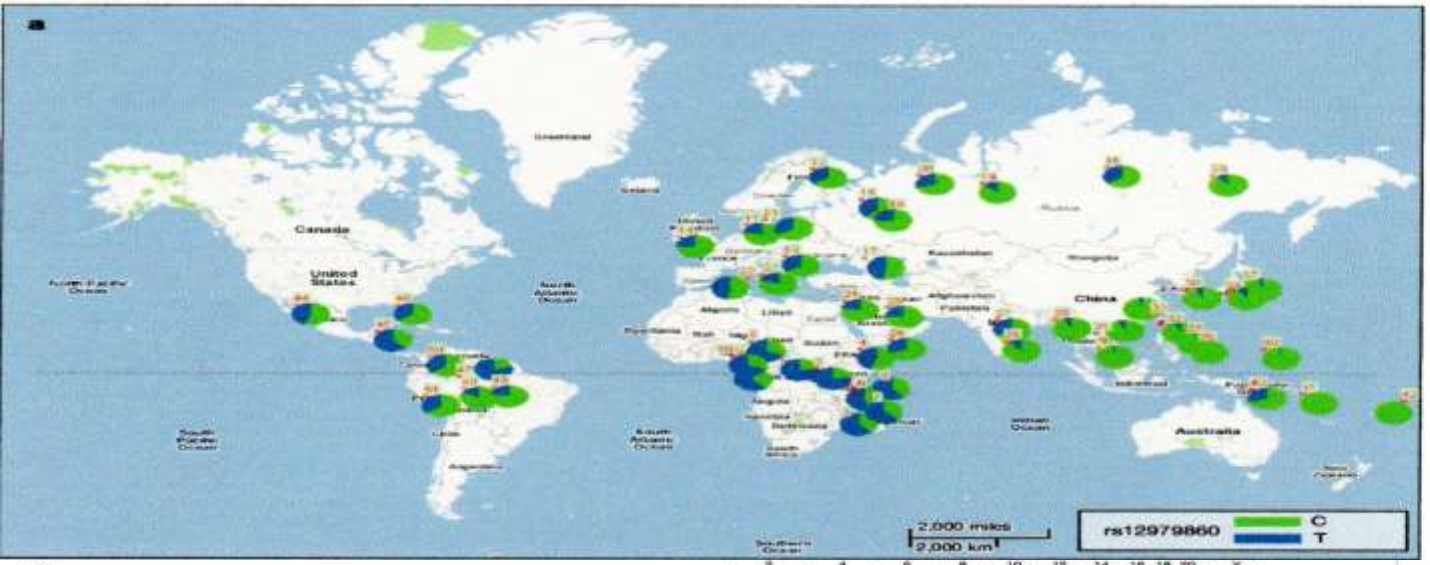

Figure 2 | Sampling locations, allele frequencies and degree of regional differentiation of the rs12979860 C allele. **a**, The numbers identifying populations are given in Table 3. The pie charts show the frequency of the C (green) and T (blue) alleles in each population sampled. **b**, Frequency distribution of F_{ST} values for 1,062 SNPs from 32 of the samples grouped into 6 regions (Africa, Europe, south Asia, southeast Asia, east Asia, Oceania). The red arrow indicates the position of the estimated F_{ST} for rs12979860.

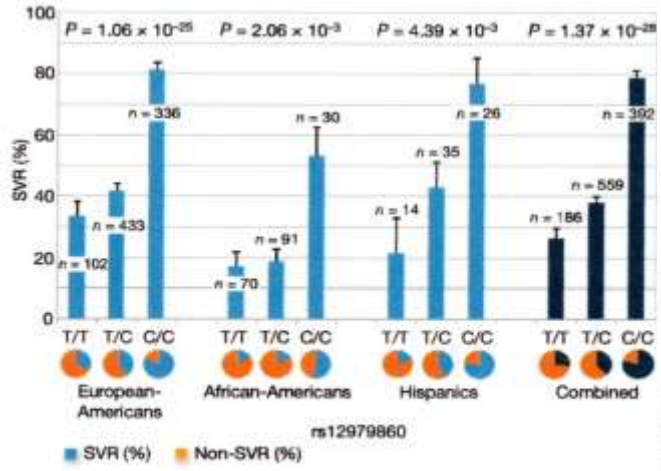

Figure 1 | Percentage of SVR by genotypes of rs12979860. Data are percentages + s.e.m.

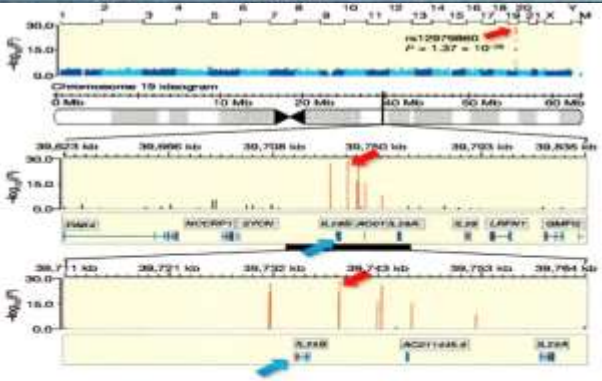

Figure 2 | Genomic overview of the region of 19q13.13 surrounding the genome-wide significant determinant of response to treatment and including the *IL28B* gene. The top panel shows a genome-wide view of the *P* values [$-\log_{10}(P)$]. Panels below show all genotyped SNPs in the region of significance and the structures of the surrounding genes. The SNPs that show genome-wide significant association with SVR are marked in red. The polymorphism rs12979860 (red arrow) is 3 kb upstream to the gene encoding IFN-λ-3 (*IL28B*, blue arrow). Other SNPs in the same region showing genome-wide significant *P* values largely reflect the same signal (Supplementary Information IX). The results were annotated using the WGAViewer software[17].

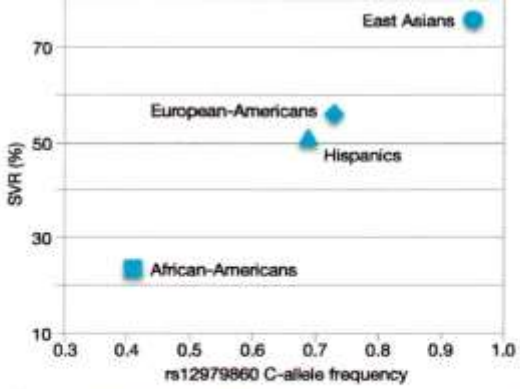

Figure 3 | Rate of SVR and rs12979860 C-allele frequency in diverse ethnic groups. The SVR rate in East Asians is adopted from Liu *et al.*[7]. Sample sizes for C-allele frequency: $n = 61$ (African-Americans); $n = 271$ (European-Americans); $n = 16$ (Hispanics); $n = 107$ (East Asians); sample sizes for SVR rate: $n = 191$ (African-Americans); $n = 871$ (European-Americans); $n = 75$ (Hispanics); $n = 154$ (East Asians).

Detection of a Gammaretrovirus, XMRV, in the Human Population: Open Questions and Implications for Xenotransplantation

Joachim Denner

Posted: 04/22/2010; Retrovirology. 2010;7:16

Abstract and Introduction

Abstract

XMRV (xenotropic murine leukaemia virus-related virus) is a gammaretrovirus that has been detected in human patients with prostate carcinoma, chronic fatigue syndrome (CFS) and also in a small percentage of clinically healthy individuals. It is not yet clear whether the distribution of this virus is primarily limited to the USA or whether it is causally associated with human disease. If future investigations confirm a broad distribution of XMRV and its association with disease, this would have an impact on xenotransplantation of porcine tissues and organs. Xenotransplantation is currently being developed to compensate for the increasing shortage of human material for the treatment of tissue and organ failure but could result in the transmission of porcine pathogens. Maintenance of pathogen-free donor animals will dramatically reduce this risk, but some of the porcine endogenous retroviruses (PERVs) found in the genome of all pigs, can produce infectious virus and infect cultured human cells. PERVs are closely related to XMRV so it is critical to develop tests that discriminate between them. Since recombination can occur between viruses, and recombinants can exhibit synergism, recipients should be tested for XMRV before xenotransplantation.

Questions Concerning XMRV Detection

SARS

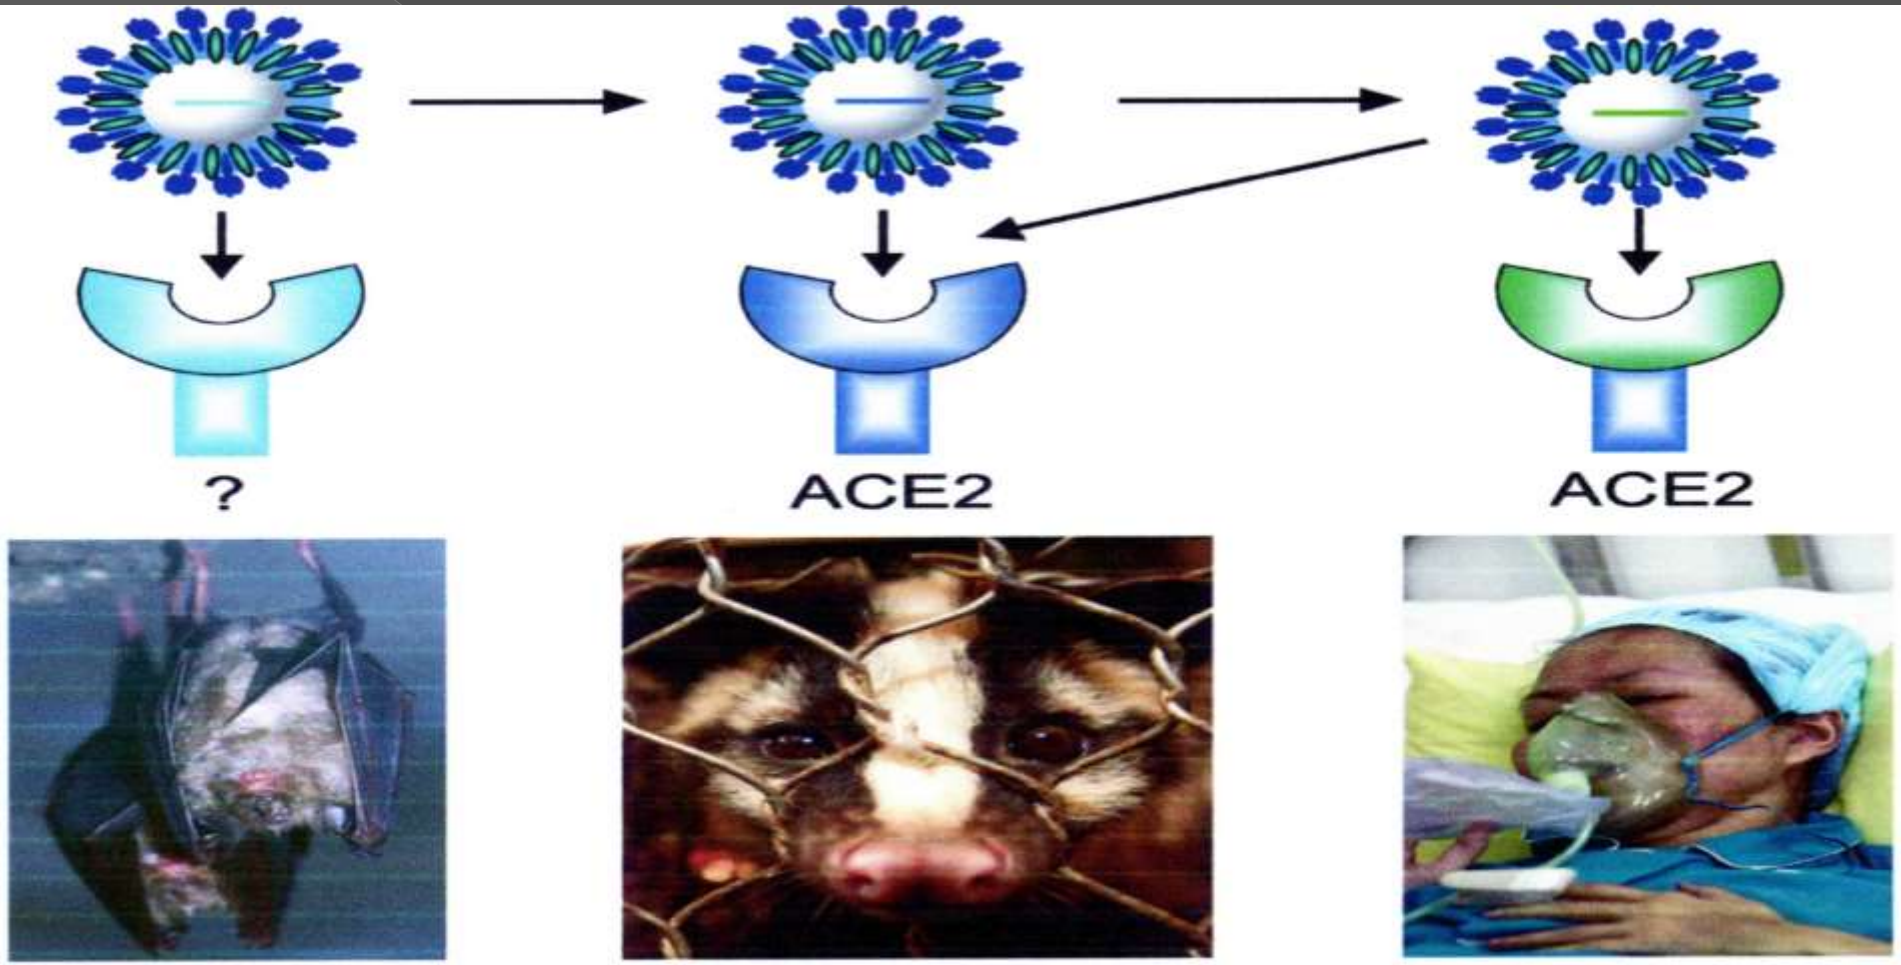

Figure 2. Zoonotic transmission of SARS-CoV. Genomic analyses provided evidence that genetic changes in the spike gene of SARS-CoV from bats (left) and civet cats (center) are essential for the animal-to-human transmission (horizontal arrows). Species-to-species genetic variation in the (thus far unidentified) viral receptor in bats and in the *angiotensin converting enzyme 2 (ACE2)* gene, encoding the SARS-CoV receptor in civet cats and humans also affects the efficiency with which the virus can enter cells (vertical arrows). The SARS-CoV that caused the epidemic evolved a high affinity for both civet (center) and human (right) ACE2 receptors (indicated by the single diagonal and the right side vertical arrow). Recycling of chloroquine and its hydroxyl analogue to face bacterial, fungal and viral infections in the 21st century

Jean-Marc Rolain*, Philippe Colson, Didier Raoult

Unité des Rickettsies, CNRS UMR 6020, Université de la Méditerranée, Faculté de Médecine et de Pharmacie, 27 Boulevard Jean Moulin, 13385 Marseille Cedex 5, France

Abstract

Chloroquine (CQ) and its hydroxyl analogue hydroxychloroquine (HCQ) are weak bases with a half-century long use as antimalarial agents. Apart from this antimalarial activity, CQ and HCQ have gained interest in the field of other infectious diseases. One of the most interesting mechanisms of action is that CQ leads to alkalinisation of acid vesicles that inhibit the growth of several intracellular bacteria and fungi. The proof of concept of this effect was first used to restore intracellular pH allowing antibiotic efficacy for *Coxiella burnetii*, the agent of Q fever, and doxycycline plus HCQ is now the reference treatment for chronic Q fever. There is also strong evidence of a similar effect in vitro against *Tropheryma whipplei*, the agent of Whipple's disease, and a clinical trial is in progress. Other bacteria and fungi multiply in an acidic environment and encouraging in vitro data suggest that this concept may be generalised for all intracellular organisms that multiply in an acidic environment. For viruses, CQ led to inhibition of uncoating and/or alteration of post-translational modifications of newly synthesised proteins, especially inhibition of glycosylation. These effects have been well described in vitro for many viruses, with human immunodeficiency virus (HIV) being the most studied. Preliminary in vivo clinical trials suggest that CQ alone or in combination with antiretroviral drugs might represent an interesting way to treat HIV infection. In conclusion, our review re-emphasises the paradigm that activities mediated by lysosomotropic agents may offer an interesting weapon to face present and future infectious diseases worldwide.

Keywords: Chloroquine; Hydroxychloroquine; Lysosomotropic agents; Alkalinisation; Q fever; Whipple's disease; HIV

Is the world getting better or worse?

If you want to make the world a better place, it's a good idea to find out where you're starting from. When we did just that, the results came as something of a surprise. By most measures, living standards are improving across the world, and though hundreds of millions of people still live in desperate conditions, things are moving in the right direction. Less encouragingly, the environment is clearly in trouble and armed conflict remains a major problem

The ancient holistic medical systems help the patient by balancing the "elements" of the human character. This work aims to understand the nature of these elements and the process of the physician balancing them. Using the concept of poly-ray cosmology we see that the medical systems from ancient India, China and Greek basically share the same inner structure and also the same logic of the treatment processes. We analyze the double concept of yin-yang, the Ayurvedic triadic concepts of Pitta, Kapha and Vata, the four elements of Hippocratic humoral medicine, and the five elements of Chinese medicine, and find that each of these conceptual frameworks make up a "theory" or model of the world that is a perfect wholeness, allowing the physician to interpret the world and his patient in order to identify the imbalances of his or her character that need to be treated. Independently of the system this can be a palliative treatment, if energies are only balanced in present time, or a causal cure if the physician is using the similarity principle to take his patient into regression back to the events in the personal history that originally created the imbalances (the traumas). To help the patient back to the traumas he is exposed to a small dose of the original harming stimulus; this can be an internal process like visualization supported by the therapist words, or an external process provoked by his actions. If the physician is balancing the elements without such a healing of the patient's existential core this can still momentarily help the patient by alleviating the symptoms, but it will not have a permanent effect.

O início do pensamento psiquiátrico

Com os escritos do médico grego, que viveu entre 460 a 357 a.C., começa-se a pensar que a loucura não é algo relacionado aos deuses. Hipócrates afirma que transtornos mentais possuíam causas naturais e eram passíveis de tratamento assim como outras doenças. Outros médicos gregos e romanos deram continuidade à pesquisa psiquiátrica e a descrições clínicas dos transtornos. A partir de 500 d.C., já com a Igreja Católica sendo uma força dominante, a abordagem de Hipócrates e de seus seguidores é abandonada.

GLOBALIZATION AND HEALTH

DEBATE Open Access

Rethinking the 'global' in global health: a dialectic approach

Kayvan Bozorgmehr

Abstract

Background: Current definitions of 'global health' lack specificity about the term 'global'. This debate presents and discusses existing definitions of 'global health' and a common problem inherent therein. It aims to provide a way forward towards an understanding of 'global health' while avoiding redundancy. The attention is concentrated on the dialectics of different concepts of 'global' in their application to malnutrition; HIV, tuberculosis & malaria; and maternal mortality. Further attention is payed to normative objectives attached to 'global health' definitions and to paradoxes involved in attempts to define the field.

Discussion: The manuscript identifies denotations of 'global' as 'worldwide', as 'transcending national boundaries' and as 'holistic'. A fourth concept of 'global' as 'supraterritorial' is presented and defined as 'links between the social determinants of health anywhere in the world'. The rhetorical power of the denotations impacts considerably on the object of 'global health', exemplified in the context of malnutrition; HIV, tuberculosis & malaria; and maternal mortality. The 'global' as 'worldwide', as 'transcending national boundaries' and as 'holistic' house contradictions which can be overcome by the fourth concept of 'global' as 'supraterritorial'. The 'global-local-relationship' inherent in the proposed concept coheres with influential anthropological and sociological views despite the use of different terminology. At the same time, it may be assembled with other views on 'global' or amend apparently conflicting ones. The author argues for detaching normative objectives from 'global health' definitions to avoid so called 'entanglement-problems'. Instead, it is argued that the proposed concept constitutes an un-euphemistical approach to describe the inherently politicised field of 'global health'.

Summary: While global-as-worldwide and global-as-transcending-national-boundaries are misleading and produce redundancy with public and international health, global-as-supraterritorial provides 'new' objects for research, education and practice while avoiding redundancy. Linked with 'health' as a human right, this concept preserves the rhetorical power of the term 'global health' for more innovative forms of study, research and practice. The dialectic approach reveals that the contradictions involved in the different notions of the term 'global' are only of apparent nature and not exclusive, but have to be seen as complementary to each other if expected to be useful in the final step.

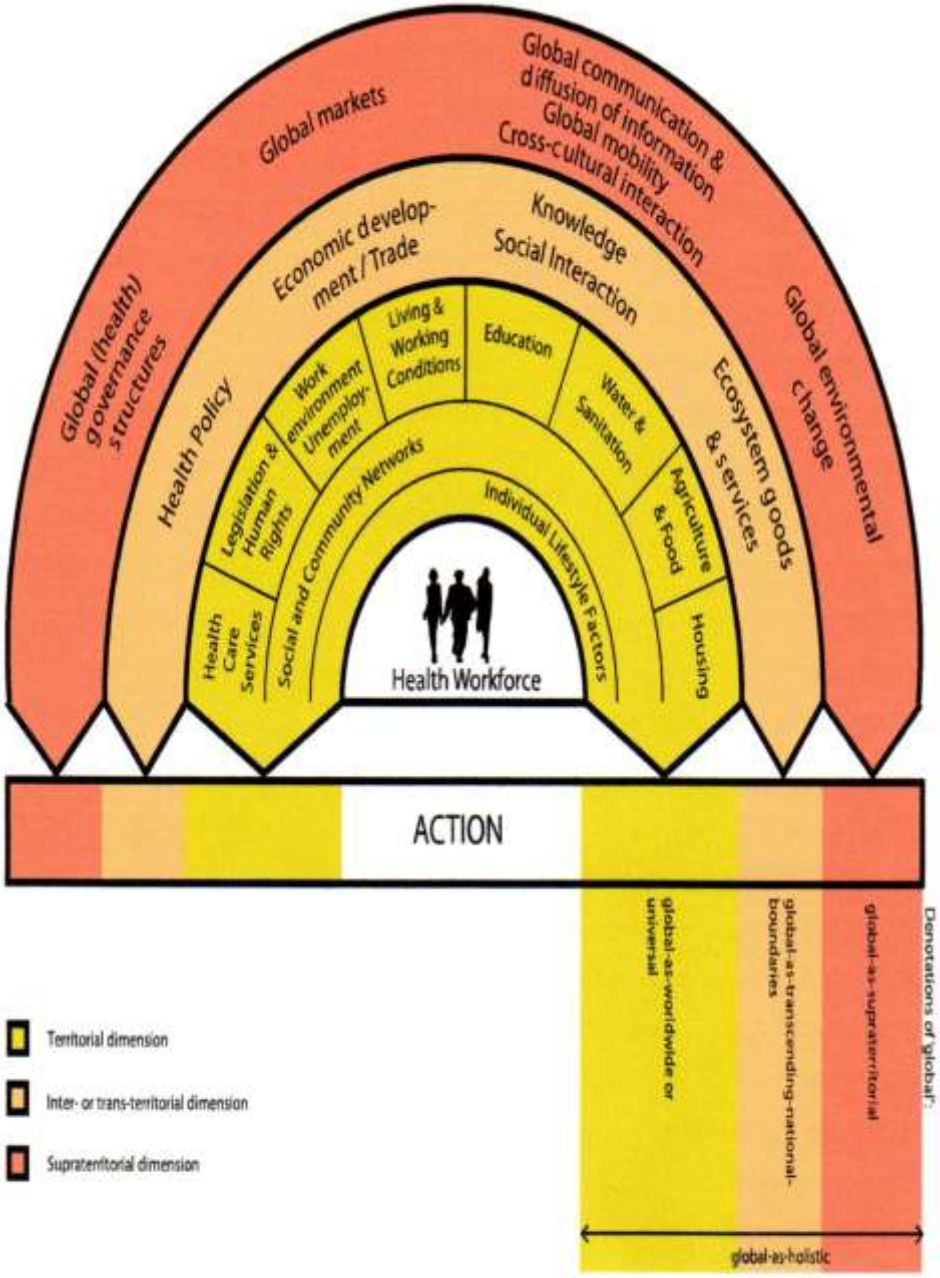

Figure 1 Concept of global health. Territorial dimension: includes for example determinants on territorial units such as community upto state or national units; Inter- or trans-territorial dimension: includes for example determinants which link and/or transcend territorial units, e.g. national borders; Supraterritorial dimension: includes social, political, economic and cultural links between determinants of health anywhere in the world regardless of territory in terms of geography.
