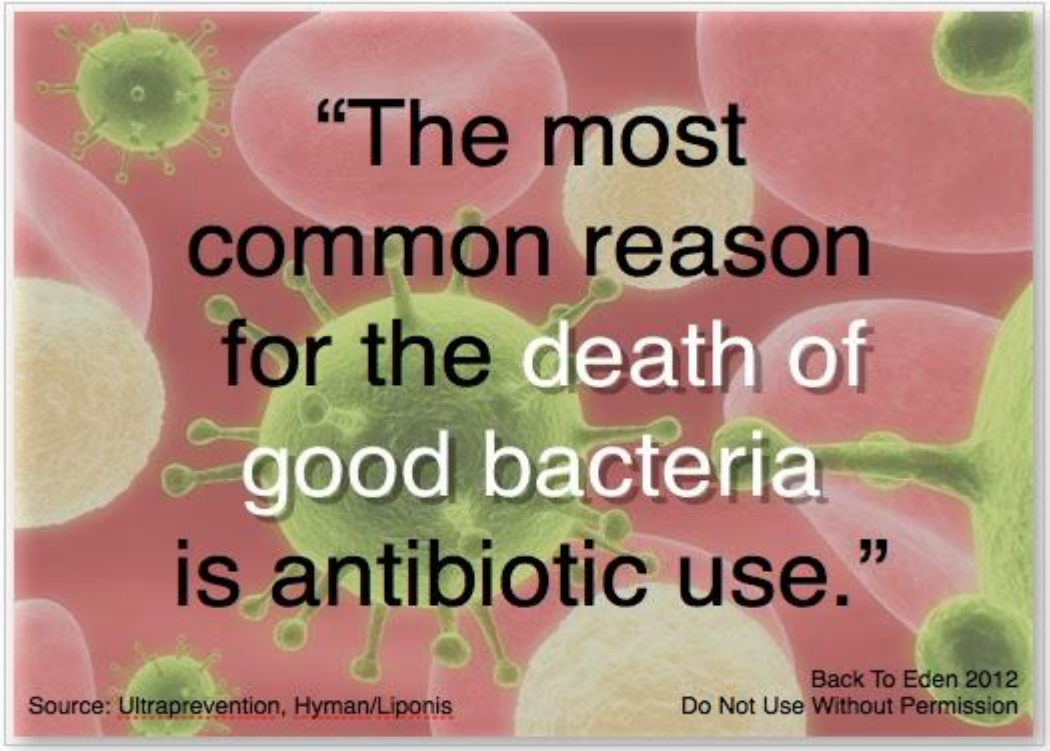
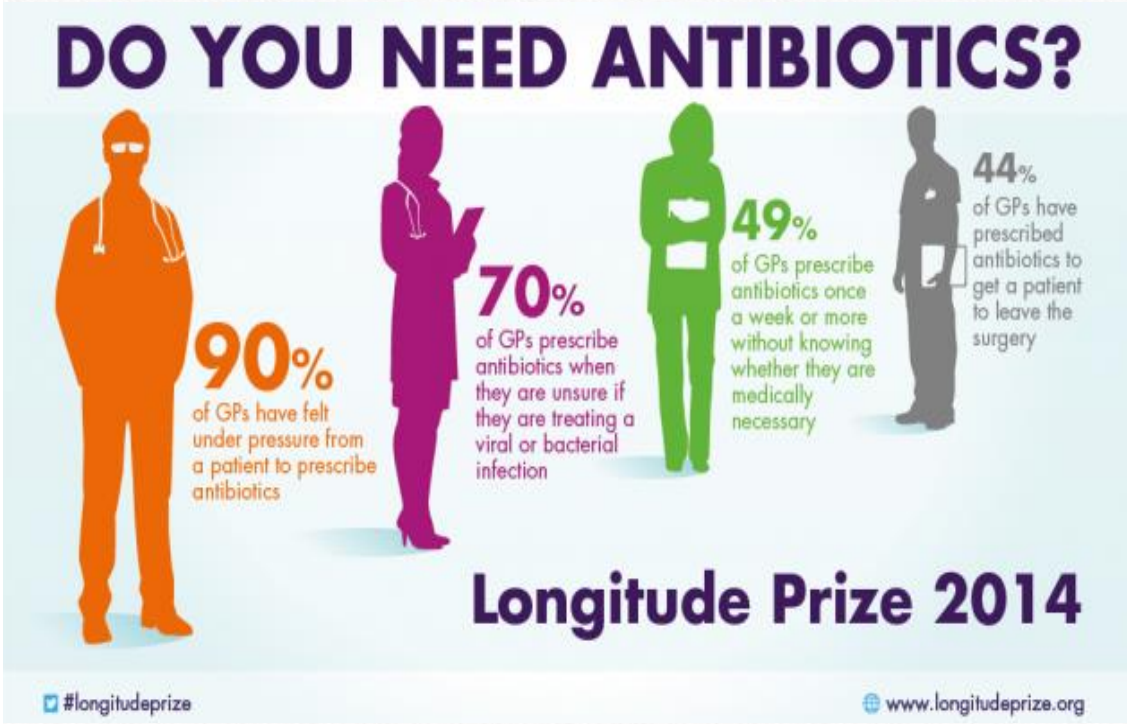
Presidente Interino da CCIPRA

INTRODUÇÃO



"The most common reason for the death of good bacteria is antibiotic use."
Source: Ultraprevention, Hyman/Liponis
Back To Eden 2012
Do Not Use Without Permission



DO YOU NEED ANTIBIOTICS?
90% of GPs have felt under pressure from a patient to prescribe antibiotics
70% of GPs prescribe antibiotics when they are unsure if they are treating a viral or bacterial infection
49% of GPs prescribe antibiotics once a week or more without knowing whether they are medically necessary
44% of GPs have prescribed antibiotics to get a patient to leave the surgery

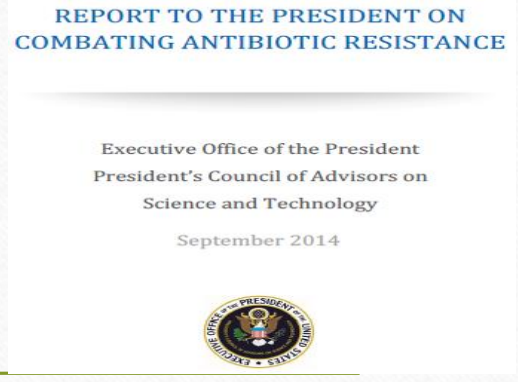
Um mero exercício de memória …



- ***"Para um cidadão americano do séc. XXI, é muito difícil imaginar o que era o mundo antes da existência dos antibióticos. No início do séc. XX, cerca de 9 em 1.000 mulheres parturientes morriam, 40% das quais por sépsis. Nalgumas cidades, 30% das crianças morriam no 1º ano de vida. 1 em cada 9 pessoas que tivessem uma infeção com alguma gravidade falecia, mesmo nos casos que atingiam exclusivamente a pele. A mortalidade da pneumonia era de 30% e a da meningite de 70%. As otites causavam frequente surdez, as amigdalites complicavam-se muitas vezes de febre remática e esta de insuficiência cardíaca. Os procedimentos cirúrgicos complicavam-se com muita frequência de processos infeciosos com elevada morbilidade e mortalidade associadas."***

- ***"O panorama mudou posteriormente de forma radical por três factos decisivos: Melhoria das condições sanitárias gerais, a vacinação em massa e a descoberta dos antibióticos. Ao longo do s. XX, as mortes por causa infeciosa diminuíram bastante, tendo contribuído para um aumento da esperança de vida em cerca de 29 anos. Os antimicrobianos, em particular, permitiram salvar anualmente muitos milhões de vidas. Primeiramente desenvolvidos na década de 30, a sua comercialização expandiu-se vertiginosamente na década seguinte. Conduziram a uma série de outros avanços nos cuidados médicos, designadamente no domínio cirúrgico (queimados, transplantados, intervencionados ao caração, etc.), através da prevenção e tratamento das complicações infeciosas associadas."***

Norma de Vigilância Epidemiológica das Resistências aos Antimicrobianos

- ❑ Ao INSA compete verificar e registar a receção dos microrganismos. A DGS e o INSA tomam conhecimento da notificação do microrganismo "alerta" em simultâneo. O INSA acusará a receção da mesma aos notificadores;
- ❑ O INSA informa a DGS e o Laboratório de origem sobre a confirmação do resultado do microrganismo "alerta" isolado;
- ❑ O INSA envia à DGS os resultados acumulados sobre os microrganismos "problema" com uma periodicidade não superior a 6 meses;
- ❑ A DGS promove o contato com o Laboratório de Microbiologia e com os GCL-PPCIRA da Instituição de origem para que, localmente:
  - exista notificação interna da deteção do microrganismo para a Direção Clínica e Direção de Enfermagem;
  - sejam adotadas medidas adequadas para o controlo e prevenção de transmissão cruzada;
  - seja disponibilizada colaboração técnico-científica

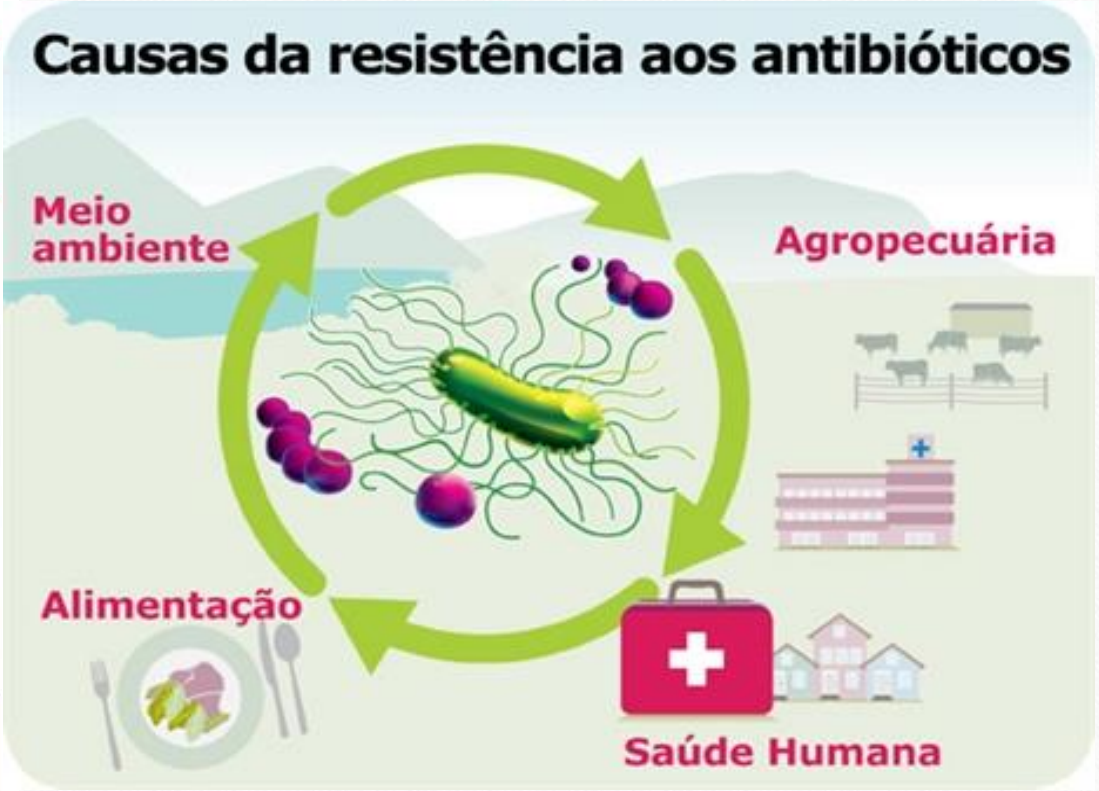
O PROBLEMA em PORTUGAL



EUROPEAN ANTIBIOTIC AWARENESS DAY

A European Health Initiative

ecdc

Summary of the latest data on antibiotic resistance in the European Union

November 2013

Highlights on antibiotic resistance

- Antibiotic resistance is a serious threat to public health in Europe, leading to increasing healthcare costs, prolonged hospital stays, treatment failures, and sometimes death.
- Over the last four years (2009 to 2012), resistance to third-generation cephalosporins in *K. pneumoniae* and *E. coli* increased significantly at EU/EEA level. Combined resistance to third-generation cephalosporins and two other important antimicrobial groups (fluoroquinolones and aminoglycosides) also increased significantly at EU/EEA level for *K. pneumoniae*, but not for *E. coli*.
- The increasing trend of combined resistance in *K. pneumoniae* means that only a few therapeutic options (e.g., carbapenems) remain available for treatment of infected patients.
- Carbapenems form a major last-line class of antibiotics to treat infections with multidrug-resistant Gram-negative bacteria such as *K. pneumoniae* and *E. coli*, both common causes of pneumonia, urinary tract infections and bloodstream infections. However, the percentage of carbapenem-resistant *K. pneumoniae* is already high and increasing in some countries in the EU.
- Antimicrobial resistance data for *Acinetobacter* spp. are available in EARS-Net for the first time. Data for 2012 show large inter-country variations in Europe, and high levels of resistance (>25%) to carbapenems in nearly half of the reporting countries.
- In contrast, in the past few years, the percentage of meticillin-resistant *Staphylococcus aureus* (MRSA) has shown a significant decreasing trend at EU/EEA level, and either a continuous decrease or a stabilising trend was observed in most EU/EEA countries during the last four years. Nevertheless, MRSA remains above 25% in almost one fourth of the reporting countries, mainly in southern and eastern Europe.
- Prudent antibiotic use and comprehensive infection control strategies targeting all healthcare sectors (acute care hospitals, long-term care facilities and ambulatory care) are the cornerstones of effective interventions that aim to prevent selection and transmission of antibiotic-resistant bacteria.

MAJOR ARTICLE

Quality and Strength of Evidence of the Infectious Diseases Society of America Clinical Practice Guidelines

Abdur Rahman Khan,[1] Sobia Khan, Valerie Zimmerman, Larry M. Baddour,[3] and Imad M. Tleyjeh[1,2,3,4]

[1]Division of Infectious Diseases, Department of Medicine, and [2]Research Centre, King Fahd Medical City, Riyadh, Saudi Arabia; and [3]Division of Infectious Diseases, Department of Medicine, and [4]Division of Epidemiology, Department of Health Sciences Research, Mayo Clinic, Rochester, Minnesota

(See the editorial commentary by Deresinski, on pages 1157–1159.)

Objective. To describe the distribution and temporal trends of the quality and strength of evidence supporting recommendations in the Infectious Diseases Society of America (IDSA) clinical practice guidelines.

Methods. Guidelines either issued or endorsed by IDSA from March 1994 to July 2009 were evaluated using the IDSA–US Public Health Service Grading System. In this system, the letters A–E signify the strength of the recommendation, and numerals I–III indicate the quality of evidence supporting these recommendations. The distribution of the guideline recommendations among strength of recommendation and quality of evidence classes was quantified. Temporal changes between the first and current guideline version were evaluated.

Results. Approximately one-half (median, 50.0%; interquartile range [IQR], 38.1%–58.6%) of the recommendations in the current guidelines are supported by level III evidence (derived from expert opinion). Evidence from observational studies (level II) supports 31% of recommendations (median, 30.9%; IQR, 23.3%–43.2%), whereas evidence based on ≥1 randomized clinical trial (level I) constitutes 16% of the recommendations (median, 15.8%; IQR, 5.8%–28.3%). The strength of recommendation was mainly distributed among classes A (median, 41.5%; IQR, 28.7%–55.6%) and B (median, 40.3%; IQR, 27.1%–47.9%). Among guidelines with ≥1 revised version, the recommendations moved proportionately toward more level I evidence (+12.4%). Consequently, there was a proportional increase in class A recommendations (+11.1%) with a decrease in class C recommendations (–23.5%).

Conclusions. The IDSA guideline recommendations are primarily based on low-quality evidence derived from nonrandomized studies or expert opinion. These findings highlight the limitations of current clinical infectious diseases research that can provide high-quality evidence. There is an urgent need to support high-quality research to strengthen the evidence available for the formulation of guidelines.

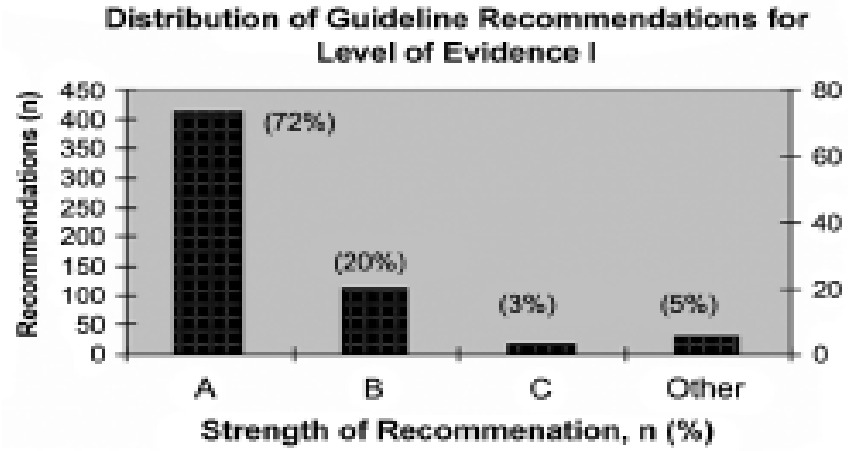

Figure 1. Distribution of the strength (classes) of recommendations across the level of evidence I.

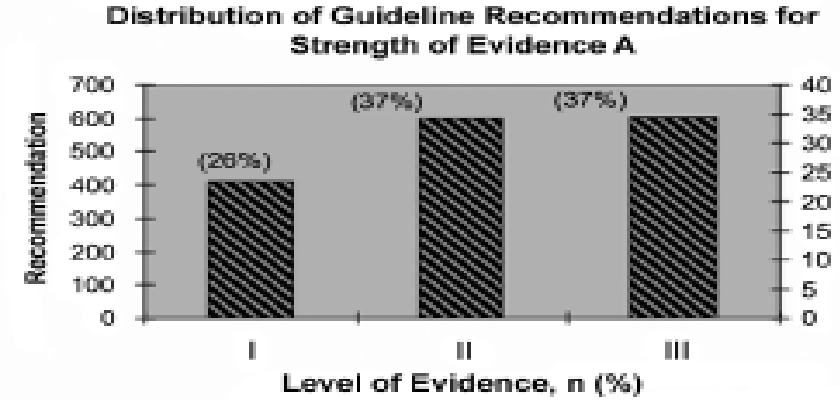

Figure 2. Distribution of the levels of evidence across the strength (classes) of recommendation A.

Abstract: Antibiotic resistance can be reduced by using antibiotics prudently based on guidelines of antimicrobial stewardship programs (ASPs) and various data such as pharmacokinetic (PK) and pharmacodynamic (PD) properties of antibiotics, diagnostic testing, antimicrobial susceptibility testing (AST), clinical response, and effects on the microbiota, as well as by new antibiotic developments. The controlled use of antibiotics in food animals is another cornerstone among efforts to reduce antibiotic resistance. All major resistance-control strategies recommend education for patients, children (e.g., through schools and day care), the public, and relevant healthcare professionals (e.g., primary-care physicians, pharmacists, and medical students) regarding unique features of bacterial infections and antibiotics, prudent antibiotic prescribing as a positive construct, and personal hygiene (e.g., handwashing). The problem of antibiotic resistance can be minimized only by concerted efforts of all members of society for ensuring the continued efficiency of antibiotics.

Keywords: antibiotic resistance; strategy; antibiotic prescribing; antimicrobial stewardship programs; education; hygiene; food animal; new antibiotics

Figure 5. Strategies to minimize antibiotic resistance. Education is the very important strategy. The multidisciplinary core group, including physicians, pharmacists, microbiologists, epidemiologists and infectious disease specialists, can be the teachers educating various members of society. ASPs, PK/PD, and MIC/MPC mean antimicrobial stewardship programs, pharmacokinetic/pharmacodynamics properties of drug, and the minimum inhibitory concentration/the mutant prevention concentration, respectively.

Burden of Antibiotic Resistance in Common Infectious Diseases: Role of Antibiotic Combination Therapy

KISHOR C MEHTA[1], RAMESH R DARGAD[2], DHAMMRAJ M BORADE[3], ONKAR C SWAMI[4]

ABSTRACT

Globally, antimicrobial resistance is alarming concern especially in commonly reported disease entities like respiratory tract infection, enteric fever and infections associated with gram-negative bacilli (GNB). Rational use of antimicrobial drugs reported significant decrease in bacterial burden and may also reduce the risk of disease progression. However, at times in particular indication, certain patient and pathogen factor limits the selection and use of specific antibiotic therapy while in some case, due to presence of additional risk factor, aggressive therapy is required to achieve clinical reemission and prevent complications. Delay in start of suitable antibiotic therapy is another imperative factor for treatment failure and rise of drug resistance.

With rapidly increasing antibiotic resistance and decline in new antibiotic drug development, the toughest challenge remains to maintain and preserve the efficacy of currently available antibiotics. Therefore, the best rational approach to fight these infections is to 'hit early and hit hard' and kills drug-susceptible bacteria before they become resistant. The preferred approach is to deploy two antibiotics that produce a stronger effect in combination than if either drug were used alone. Various society guidelines in particular indications also justify and recommend the use of combination of antimicrobial therapy. Combination therapies have distinct advantage over monotherapy in terms of broad coverage, synergistic effect and prevention of emergence of drug resistance.

Author	Cohort	Study design	n	Drug Combination	Outcome
Weiss et al., [8]	Pneumococcal bacteremia	Monocenter, retrospective	95	β-lactam plus macrolide	Lower mortality with combination
Dudas et al., [15]	CAP	Multicenter, prospective	2963	β-lactam plus macrolide	Lower mortality and reduced length of stay

SUPPLEMENT ARTICLE

Use of Electronic Health Records and Clinical Decision Support Systems for Antimicrobial Stewardship

Graeme N. Forrest,[1] Trevor C. Van Schooneveld,[2] Ravina Kullar,[3] Lucas T. Schulz,[4] Phu Duong,[3] and Michael Postelnick[5]

[1]Division of Infectious Diseases, Portland Veterans Affairs Medical Center, Portland, Oregon; [2]University of Nebraska Medical Center, Omaha; [3]Global Medical Affairs, Cubist Pharmaceuticals, Lexington, Massachusetts; [4]University of Wisconsin Hospital and Clinics, Madison; and [5]Northwestern Memorial Hospital, Chicago, Illinois

Electronic health records (EHRs) and clinical decision support systems (CDSSs) have the potential to enhance antimicrobial stewardship. Numerous EHRs and CDSSs are available and have the potential to enable all clinicians and antimicrobial stewardship programs (ASPs) to more efficiently review pharmacy, microbiology, and clinical data. Literature evaluating the impact of EHRs and CDSSs on patient outcomes is lacking, although EHRs with integrated CDSSs have demonstrated improvements in clinical and economic outcomes. Both technologies can be used to enhance existing ASPs and their implementation of core ASP strategies. Resolution of administrative, legal, and technical issues will enhance the acceptance and impact of these systems. EHR systems will increase in value when manufacturers include integrated ASP tools and CDSSs that do not require extensive commitment of information technology resources. Further research is needed to determine the true impact of current systems on ASP and the ultimate goal of improved patient outcomes through optimized antimicrobial use.

Keywords. antimicrobial stewardship; clinical decision support system; electronic health record.

Table 2. Clinical Decision Support Systems and Patient Outcomes

Reference Number	Study Design	Software	Setting	Results	Notes
[9]	Pre–Post	TheraDoc	ICU	Significant declines in antibiotic susceptibility mismatches, duration of excess drug doses, and orders for antibiotics to which the patient was allergic ($P < .01$). Also had a 70% reduction in ADE ($P = .018$).	No differences in mortality between groups
[10]	Prospective	TheraDoc	Inpatient	22.8% decline in antibiotic use, a $70 per-patient decrease in antibiotic costs, a decline in antibiotic adverse events, and a decline in hospital mortality over a 7-year period (3.65% to 2.65%, $P < .001$).	Time period evaluated was from 1988 to 1994
[56]	Cluster randomized	TheraDoc	Community clinics	Antibiotic prescribing rate declined from 84.1 to 75.3 prescriptions per 100 person-years ($P = .03$). Also reduced inappropriate antibiotic prescribing, from 32% to 5% ($P = .03$).	Macrolides reduced 28%, cephalosporins 7%, and penicillins 6%
[57]	Pre–post	Unknown	PPRnet—outpatients	Inappropriate antibiotic use declined 0.6% for ARI and 16.6% for broad antibiotics in adults.	Modest effect
[58]	Prospective interventional	Unknown	PPRnet	Antibiotic use did not change (+1.57%), decrease in broad antibiotic use for ARI (−16%).	Decreased broad antibiotic use
[59]	Retrospective observational	Unknown	Veterans Affairs—outpatients	Increase in antibiotic usage (0.63 to 0.72, $P = .001$).	No effect seen targeting ARI antibiotics
[60]	Prospective	Local program	Outpatients	Overall antibiotic prescribing 39% vs non-CDSS of 43%. ARI was 54% vs 59%.	CDSS form only used in 6% of ARI visits
[61]	Prospective	TheraDoc	Pediatrics	59% reduction in erroneous antimicrobial use, 28% decline in excess dose-days. No change in ADE or susceptibility mismatches.	
[62]	Cluster-randomized study	TREAT	Inpatient	Better empiric antibiotic therapy (70% vs 57%, $P < .001$). Length of stay and costs (−12%) also reduced.	No impact on mortality
[63]	Survival analysis	TREAT	Inpatient, single center	The ITT group 180-day survival in the control group was 68% vs 71% in the intervention group ($P = .1$). In the PP analysis, the survival percentages were 68% vs 74% ($P = .04$).	Analysis of only 1 center of whole study that analyzed 30-day mortality
[64]	Prospective	Antibiograms	ICU	Increased susceptibility to imipenem (18.3%/year) and gentamicin (11.6%/year).	No clinical outcomes data.

Abbreviations: ADE, adverse drug event; ARI, acute respiratory infection; CDSS, clinical decision support system; ICU, intensive care unit; ITT, intent to treat; PP, per protocol; PPRnet, Practice Partners Research Network.

Individualised antibiotic dosing for patients who are critically ill: challenges and potential solutions

Jason A Roberts, Mohd H Abdul-Aziz, Jeffrey Lipman, Johan W Mouton, Alexander A Vinks, Timothy W Felton, William W Hope, Andras Farkas, Michael N Neely, Jerome J Schentag, George Drusano, Otto R Frey, Ursula Theuretzbacher, Joseph L Kuti, on behalf of The International Society of Anti-Infective Pharmacology and the Pharmacokinetics and Pharmacodynamics Study Group of the European Society of Clinical Microbiology and Infectious Diseases

Infections in critically ill patients are associated with persistently poor clinical outcomes. These patients have severely altered and variable antibiotic pharmacokinetics and are infected by less susceptible pathogens. Antibiotic dosing that does not account for these features is likely to result in suboptimum outcomes. In this Review, we explore the challenges related to patients and pathogens that contribute to inadequate antibiotic dosing and discuss how to implement a process for individualised antibiotic therapy that increases the accuracy of dosing and optimises care for critically ill patients. To improve antibiotic dosing, any physiological changes in patients that could alter antibiotic concentrations should first be established; such changes include altered fluid status, changes in serum albumin concentrations and renal and hepatic function, and microvascular failure. Second, antibiotic susceptibility of pathogens should be confirmed with microbiological techniques. Data for bacterial susceptibility could then be combined with measured data for antibiotic concentrations (when available) in clinical dosing software, which uses pharmacokinetic/pharmacodynamic derived models from critically ill patients to predict accurately the dosing needs for individual patients. Individualisation of dosing could optimise antibiotic exposure and maximise effectiveness.

REVIEW Open Access

How do we use therapeutic drug monitoring to improve outcomes from severe infections in critically ill patients?

Gloria Wong[1†], Fekade Bruck Sime[2,3†], Jeffrey Lipman[1,4] and Jason A Roberts[1,2,4*]

Abstract

High mortality and morbidity rates associated with severe infections in the critically ill continue to be a significant issue for the healthcare system. In view of the diverse and unique pharmacokinetic profile of drugs in this patient population, there is increasing use of therapeutic drug monitoring (TDM) in attempt to optimize the exposure of antibiotics, improve clinical outcome and minimize the emergence of antibiotic resistance. Despite this, a beneficial clinical outcome for TDM of antibiotics has only been demonstrated for aminoglycosides in a general hospital patient population. Clinical outcome studies for other antibiotics remain elusive. Further, there is significant variability among institutions with respect to the practice of TDM including the selection of patients, sampling time for concentration monitoring, methodologies of antibiotic assay, selection of PK/PD targets as well as dose optimisation strategies. The aim of this paper is to review the available evidence relating to practices of antibiotic TDM, and describe how TDM can be applied to potentially improve outcomes from severe infections in the critically ill.

Abstract

There is an urgent need for novel antibiotics to treat life-threatening infections caused by bacterial 'superbugs'. Validated *in vitro* pharmacokinetic/pharmacodynamic (PK/PD) and animal infection models have been employed to identify the most predictive PK/PD indices and serve as key tools in the antibiotic development process. The results obtained can be utilized for optimizing study designs in order to minimize the cost and duration of clinical trials. This review outlines the key *in vitro* PK/PD and animal infection models which have been extensively used in antibiotic discovery and development. These models have shown great potential in accelerating drug development programs and will continue to make significant contributions to antibiotic development.

Abstract

Society faces a crisis of rising antibiotic resistance even as the pipeline of new antibiotics has been drying up. Antibiotics are a public trust; every individual's use of antibiotics affects their efficacy for everyone else. As such, responses to the antibiotic crisis must take a societal perspective. The market failure of antibiotics is due to a combination of scientific challenges to discovering and developing new antibiotics, unfavorable economics, and a hostile regulatory environment. Scientific solutions include changing the way we screen for new antibiotics. More transformationally, developing new treatments that seek to disarm pathogens without killing them, or that modulate the host inflammatory response to infection, will reduce selective pressure and hence minimize resistance emergence. Economic transformation will require new business models to support antibiotic development. Finally, regulatory reform is needed so that clinical development programs are feasible, rigorous, and clinically relevant. Pulmonary and critical care specialists can have tremendous impact on the continued availability of effective antibiotics. Encouraging use of molecular diagnostic tests to allow pathogen-targeted, narrow-spectrum antibiotic therapy, using short rather than unnecessarily long course therapy, reducing inappropriate antibiotic use for probable viral infections, and reducing infection rates will help preserve the antibiotics we have for future generations.

The emergence of drug-resistant bacteria threatens to revert humanity back to the preantibiotic era. Even now, multidrug-resistant bacterial infections annually result in millions of hospital days, billions in healthcare costs, and, most importantly, tens of thousands of lives lost. As many pharmaceutical companies have abandoned antibiotic development in search of more lucrative therapeutics, academic researchers are uniquely positioned to fill the pipeline. Traditional high-throughput screens and lead-optimization efforts are expensive and labor intensive. Computer-aided drug-discovery techniques, which are cheaper and faster, can accelerate the identification of novel antibiotics, leading to improved hit rates and faster transitions to preclinical and clinical testing. The current review describes two machine-learning techniques, neural networks and decision trees, that have been used to identify experimentally validated antibiotics. We conclude by describing the future directions of this exciting field.

Abstract: The continuing emergence of antibiotic-resistant pathogens is a concern to human health and highlights the urgent need for the development of alternative therapeutic strategies. Quorum sensing (QS) regulates virulence in many bacterial pathogens, and thus, is a promising target for antivirulence therapy which may inhibit virulence instead of cell growth and division. This means that there is little selective pressure for the evolution of resistance. Many natural quorum quenching (QQ) agents have been identified. Moreover, it has been shown that many microorganisms are capable of producing small molecular QS inhibitors and/or macromolecular QQ enzymes, which could be regarded as a strategy for bacteria to gain benefits in competitive environments. More than 30 species of marine QQ bacteria have been identified thus far, but only a few of them have been intensively studied. Recent studies indicate that an enormous number of QQ microorganisms are undiscovered in the highly diverse marine environments, and these marine microorganism-derived QQ agents may be valuable resources for antivirulence therapy.

Antimicrobial peptides

MARTIN MALMSTEN

Department of Pharmacy, Uppsala University, Uppsala, Sweden

Abstract

With increasing antibiotics resistance, there is an urgent need for novel infection therapeutics. Since antimicrobial peptides provide opportunities for this, identification and optimization of such peptides have attracted much interest during recent years. Here, a brief overview of antimicrobial peptides is provided, with focus placed on how selected hydrophobic modifications of antimicrobial peptides can be employed to combat also more demanding pathogens, including multi-resistant strains, without conferring unacceptable toxicity.

REVIEW

Strategies for combating bacterial biofilm infections

Hong Wu[1,2], Claus Moser[1], Heng-Zhuang Wang[1], Niels Høiby[1,2] and Zhi-Jun Song[1,3]

Formation of biofilm is a survival strategy for bacteria and fungi to adapt to their living environment, especially in the hostile environment. Under the protection of biofilm, microbial cells in biofilm become tolerant and resistant to antibiotics and the immune responses, which increases the difficulties for the clinical treatment of biofilm infections. Clinical and laboratory investigations demonstrated a perspicuous correlation between biofilm infection and medical foreign bodies or indwelling devices. Clinical observations and experimental studies indicated clearly that antibiotic treatment alone is in most cases insufficient to eradicate biofilm infections. Therefore, to effectively treat biofilm infections with currently available antibiotics and evaluate the outcomes become important and urgent for clinicians. The review summarizes the latest progress in treatment of clinical biofilm infections and scientific investigations, discusses the diagnosis and treatment of different biofilm infections and introduces the promising laboratory progress, which may contribute to prevention or cure of biofilm infections. We conclude that, an efficient treatment of biofilm infections needs a well-established multidisciplinary collaboration, which includes removal of the infected foreign bodies, selection of biofilm-active, sensitive and well-penetrating antibiotics, systemic or topical antibiotic administration in high dosage and combinations, and administration of anti-quorum sensing or biofilm dispersal agents.

The discovery and therapeutic use of antibiotics made a major contribution to the reduction of human morbidity and mortality. However, the growing resistance to antibiotics has become a matter of huge concern. In this study we aimed to develop an innovative approach to treat bacterial infections utilizing two components: the human antibacterial peptide β-defensin-3 (BD3) and the bacterial protein flagellin (F). This combination was designed to provide an efficient weapon against bacterial infections with the peptide killing the bacteria directly, while the flagellin protein triggers the immune system and acts against bacteria escaping from the peptide's action. We designed, expressed and purified the fusion protein flagellin BD3 (FBD3) and its two components, the F protein and the native BD3 peptide. FBD3 fusion protein and native BD3 peptide had antibacterial activity *in vitro* against various bacterial strains. FBD3 and F proteins could also recognize their receptor expressed on target cells and stimulated secretion of IL-8. In addition, F and FBD3 proteins had a partial protective effect in mice infected by pathogenic *Escherichia coli* bacteria that cause a lethal disease. Moreover, we were able to show partial protection of mice infected with *E. coli* using a flagellin sequence from *Salmonella*. We also explored flagellin's basic mechanisms of action, focusing on its effects on CD4+ T cells from healthy donors. We found that F stimulation caused an increase in the mRNA levels of the Th1 response cytokines IL12A and IFNγ. In addition, F stimulation affected its own receptor.

Keywords: antibacterial peptide β-defensin-3 (BD3), flagellin (F), fusion protein (FBD3), bacterial infection, antibacterial activity, TLR5 receptor, human CD4+ T cells

Bacterial infections are raising serious concern across the globe. The effectiveness of conventional antibiotics is decreasing due to global emergence of multi-drug-resistant (MDR) bacterial pathogens. This process seems to be primarily caused by an indiscriminate and inappropriate use of antibiotics in non-infected patients and in the food industry. New classes of antibiotics with different actions against MDR pathogens need to be developed urgently. In this context, this review focuses on several ways and future directions to search for the next generation of safe and effective antibiotics compounds including antimicrobial peptides, phage therapy, phytochemicals, metalloantibiotics, lipopolysaccharide, and efflux pump inhibitors to control the infections caused by MDR pathogens.

Table 1 | Major types of antimicrobial compounds with their mechanisms of action.

Future therapy	Mechanism	Contemporary strategies to improve activity
Antimicrobial peptides	Attach and insert into membrane bilayers to form pores by "barrel-stave," "carpet," or "toroidal-pore" mechanisms. DNA and macromolecule synthesis inhibitors.	Optimization of peptide length and content of their sequences. Conversion into peptidomimetics. Generation of targeted antimicrobial peptides (Peptide antibiotic conjugation). Generation of antimicrobial peptides as prodrug candidates. Antimicrobial peptides loaded into nanoparticle or micelles for sustained release.
Phage therapy	Bacteriophages are viruses that act as pathogens against bacteria and completely lyse the bacteria.	Genetically engineered phages. Genetically engineered phase as antibiotic delivery. Engineered bacteriophage for phage targeted drug delivery. Scale up of endolysin production.
Phytochemicals	Multiple actions.	Search for novel compounds and cost-effective methods of extraction and purification of phytochemical. Transgenic production in plant and microbial system to enhance number of novel compounds. Search for endophytic fungal metabolomics for the production of novel compound of host. Synthesis and modification of natural structure and analogs.
Metalloantibiotic	Increased spectrum of conventional antibiotic action.	Synthetic or semi-synthetic antimicrobial compound development attaching metal to its structure. *In situ* reducing and capping of metal nanoparticle with enhanced antimicrobial activity.
Efflux pump inhibitor	Molecules to inhibit the active protein pump in the bacterial cell.	Chemical synthesis of effective efflux pumps inhibitor. Screening of efflux pump inhibitors from natural origin and modifying this compound synthetically. Rationally designed transmembrane peptide mimics.

Bacteriophage therapy: a potential solution for the antibiotic resistance crisis

Zhabiz Golkar, Omar Bagasra, Donald Gene Pace

South Carolina Center for Biotechnology, Claflin University, Orangeburg, United States

Abstract

The emergence of multiple drug-resistant bacteria has prompted interest in alternatives to conventional antimicrobials. One of the possible replacement options for antibiotics is the use of bacteriophages as antimicrobial agents. Phage therapy is an important alternative to antibiotics in the current era of drug-resistant pathogens. Bacteriophages have played an important role in the expansion of molecular biology and have been used as antibacterial agents since 1966. In this review, we describe a brief history of bacteriophages and clinical studies on their use in bacterial disease prophylaxis and therapy. We discuss the advantages and disadvantages of bacteriophages as therapeutic agents in this regard.

Abstract

The ability of microbes to form biofilms is an important element of their pathogenicity, and biofilm formation is a serious challenge for today's medicine. Fighting the clinical complications associated with biofilm formation is very difficult and linked to a high risk of failure, especially in a time of increasing bacterial resistance to antibiotics. Bacterial species most commonly isolated from biofilms include coagulase-negative staphylococci, *Staphylococcus aureus*, *Enterococcus faecalis*, *Enterococcus faecium*, *Escherichia coli*, *Proteus mirabilis*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa* and *Acinetobacter* spp. The frequent failure of antibiotic therapy led researchers to look for alternative methods and experiment with the use of antibacterial factors with a mechanism of action different from that of antibiotics. Experimental studies with bacteriophages and mixtures thereof, expressing lytic properties against numerous biofilm-forming bacterial species showed that bacteriophages may both prevent biofilm formation and contribute to eradication of biofilm bacteria. A specific role is played here by phage depolymerases, which facilitate the degradation of extracellular polymeric substances (EPS) and thus the permeation of bacteriophages into deeper biofilm layers and lysis of the susceptible bacterial cells. Much hope is placed in genetic modifications of bacteriophages that would allow the equipping bacteriophages with the function of depolymerase synthesis. The use of phage cocktails prevents the development of phage-resistant bacteria.

Key words: biofilm, bacteriophage, anti-biofilm activity

Cost-effectiveness and Pricing of Antibacterial Drugs

Talitha I. Verhoef* and Stephen Morris

Department of Applied Health Research, University College London, Gower Street, London WC1E 6BT, UK
**Corresponding author: Talitha Verhoef, t.verhoef@ucl.ac.uk*

Growing resistance to antibacterial agents has increased the need for the development of new drugs to treat bacterial infections. Given increasing pressure on limited health budgets, it is important to study the cost-effectiveness of these drugs, as well as their safety and efficacy, to find out whether or not they provide value for money and should be reimbursed. In this article, we systematically reviewed 38 cost-effectiveness analyses of new antibacterial agents. Most studies showed the new antibacterial drugs were cost-effective compared to older generation drugs. Drug pricing is a complicated process, involving different stakeholders, and has a large influence on cost-effectiveness. Value-based pricing is a method to determine the price of a drug at which it can be cost-effective. It is currently unclear what the influence of value-based pricing will be on the prices of new antibacterial agents, but an important factor will be the definition of 'value', which as well as the impact of the drug on patient health might also include other factors such as wider social impact and the health impact of disease.

The rising tide of antibacterial resistance and the lack of a diverse, vibrant pipeline of novel antibacterial agents is a global crisis that impairs our ability to treat life-threatening infections. The recent introduction of a tiered approach to the regulatory framework in this area offers one path to resolving some of the challenges. By drawing heavily on the predictive power of the related sciences of pharmacokinetics and pharmacodynamics, smaller, focused clinical trial programs have become possible for agents that might not otherwise have been possible to progress. There are limitations to these pathways, and they are not easy to implement, but making reliable noninferiority-based approaches available is critical to reinvigorating the global antibiotic pipeline. With the recognition of these ideas by key regulatory authorities in recent guidance, the next challenges in this area will focus on interpretive breakpoints, the extent of data in the prescribing information, ensuring that multiple agents can be progressed, and the challenge of the antibiotic business model.

Procalcitonin for diagnosis of infection and guide to antibiotic decisions: past, present and future

Philipp Schuetz[1*], Werner Albrich[2] and Beat Mueller[2]

Abstract

There are a number of limitations to using conventional diagnostic markers for patients with clinical suspicion of infection. As a consequence, unnecessary and prolonged exposure to antimicrobial agents adversely affect patient outcomes, while inappropriate antibiotic therapy increases antibiotic resistance. A growing body of evidence supports the use of procalcitonin (PCT) to improve diagnosis of bacterial infections and to guide antibiotic therapy. For patients with upper and lower respiratory tract infection, post-operative infections and for severe sepsis patients in the intensive care unit, randomized-controlled trials have shown a benefit of using PCT algorithms to guide decisions about initiation and/or discontinuation of antibiotic therapy. For some other types of infections, observational studies have shown promising first results, but further intervention studies are needed before use of PCT in clinical routine can be recommended. The aim of this review is to summarize the current evidence for PCT in different infections and clinical settings, and discuss the reliability of this marker when used with validated diagnostic algorithms.

Cost-Effectiveness of Procalcitonin-Guided Antibiotic Therapy for Outpatient Management of Acute Respiratory Tract Infections in Adults

Promising New Assays and Technologies for the Diagnosis and Management of Infectious Diseases

S. F. Mitsuma,[1,a] M. K. Mansour,[1,a] J. P. Dekker,[2] J. Kim,[2] M. Z. Rahman,[1] A. Tweed-Kent,[3] and P. Schuetz[4]

Divisions of [1]Infectious Diseases and [2]Clinical Pathology, and [3]Department of Medicine, Massachusetts General Hospital, Boston; and [4]Department of Internal Medicine, University of Basel, Kantonsspital Aarau, Switzerland

In the first decade of the 21st century, we have seen the completion of the human genome project and marked progress in the human microbiome project. The vast amount of data generated from these efforts combined with advances in molecular and biomedical technologies have led to the development of a multitude of assays and technologies that may be useful in the diagnosis and management of infectious diseases. Here, we identify several new assays and technologies that have recently come into clinical use or have potential for clinical use in the near future. The scope of this review is broad and includes topics such as the serum marker procalcitonin, gene expression profiling, matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS), and nucleic acid aptamers. Principles that underlie each assay or technology, their clinical applications, and potential strengths and limitations are addressed.

Keywords. procalcitonin; gene expression profiling; mass spectrometry; MALDI-TOF MS; sepsis.

ABSTRACT

The application of proteomics to translational and clinical microbiology is one of the most advanced frontiers in the management and control of infectious diseases and in the understanding of complex microbial systems within human fluids and districts. This new approach aims at providing, by dedicated bioinformatic pipelines, a thorough description of pathogen proteomes and their interactions within the context of human host ecosystems, revolutionizing the vision of infectious diseases in biomedicine and approaching new viewpoints in both diagnostic and clinical management of the patient.

Indeed, in the last few years, many laboratories have matured a series of advanced proteomic applications, aiming at providing individual proteome charts of pathogens, with respect to their morph and/or cell life stages, antimicrobial or antimycotic resistance profiling, epidemiological dispersion. Herein, we aim at reviewing the current state-of-the-art on proteomic protocols designed and set-up for translational and diagnostic microbiological purposes, from axenic pathogens' characterization to microbiota ecosystems' full description. The final goal is to describe applications of the most common MALDI-TOF MS platforms to advanced diagnostic issues related to emerging infections, increasing of fastidious bacteria, and generation of patient-tailored phylotypes.

Antibiotic cycling or rotation: a systematic review of the evidence of efficacy

Erwin M. Brown[1]* and Dilip Nathwani[2]

[1]*Department of Medical Microbiology, Frenchay Hospital, Bristol BS16 1LE;* [2]*Infection Unit, East Block, Ninewells Hospital and Medical School, Dundee DD1 9SY, UK*

Of the interventions designed to reduce antibiotic resistance rates in hospitals, one that is currently attracting considerable interest, particularly in the intensive care unit setting, is antibiotic cycling or rotation. Cycling is the scheduled rotation of one class of antibiotics with one or more different classes exhibiting comparable spectra of activity; in order to fulfil the definition, the cycle must be repeated. Following a search of the literature we identified 11 articles in which the authors claimed to have evaluated the efficacy of this intervention. Only four were suitable for review, but, owing to multiple methodological flaws and a lack of standardization, the results of these studies do not permit reliable conclusions regarding the efficacy of cycling. Further studies are therefore required in order to resolve this question. However, before such studies can be undertaken, there are a great many issues relating to cycling which must be addressed. For the time being, we advise against the routine implementation of this measure as a means of reducing antibiotic resistance rates.

Cycling Empirical Antibiotic Therapy in Hospitals: Meta-Analysis and Models

Pia Abel zur Wiesch[1,2]*, Roger Kouyos[1,3]*, Sören Abel[4], Wolfgang Viechtbauer[5], Sebastian Bonhoeffer[1]

1 Institute of Integrative Biology, ETH Zurich, Zurich, Switzerland, **2** Division of Global Health Equity, Brigham and Women's Hospital/Harvard Medical School, Boston, Massachusetts, United States of America, **3** Division of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, Zurich, Switzerland, **4** Division of Infectious Diseases, Brigham and Women's Hospital/Harvard Medical School, Boston, Massachusetts, United States of America, **5** Department of Psychiatry and Psychology, School for Mental Health and Neuroscience, Faculty of Health, Medicine, and Life Sciences, Maastricht University, Maastricht, The Netherlands

Abstract

The rise of resistance together with the shortage of new broad-spectrum antibiotics underlines the urgency of optimizing the use of available drugs to minimize disease burden. Theoretical studies suggest that coordinating empirical usage of antibiotics in a hospital ward can contain the spread of resistance. However, theoretical and clinical studies came to different conclusions regarding the usefulness of rotating first-line therapy (cycling). Here, we performed a quantitative pathogen-specific meta-analysis of clinical studies comparing cycling to standard practice. We searched PubMed and Google Scholar and identified 46 clinical studies addressing the effect of cycling on nosocomial infections, of which 11 met our selection criteria. We employed a method for multivariate meta-analysis using incidence rates as endpoints and find that cycling reduced the incidence rate/1000 patient days of both total infections by 4.95 [9.43–0.48] and resistant infections by 7.2 [14.00–0.44]. This positive effect was observed in most pathogens despite a large variance between individual species. Our findings remain robust in uni- and multivariate metaregressions. We used theoretical models that reflect various infections and hospital settings to compare cycling to random assignment to different drugs (mixing). We make the realistic assumption that therapy is changed when first line treatment is ineffective, which we call "adjustable cycling/mixing". In concordance with earlier theoretical studies, we find that in strict regimens, cycling is detrimental. However, in adjustable regimens single resistance is suppressed and cycling is successful in most settings. Both a meta-regression and our theoretical model indicate that "adjustable cycling" is especially useful to suppress emergence of multiple resistance. While our model predicts that cycling periods of one month perform well, we expect that too long cycling periods are detrimental. Our results suggest that "adjustable cycling" suppresses multiple resistance and warrants further investigations that allow comparing various diseases and hospital settings.

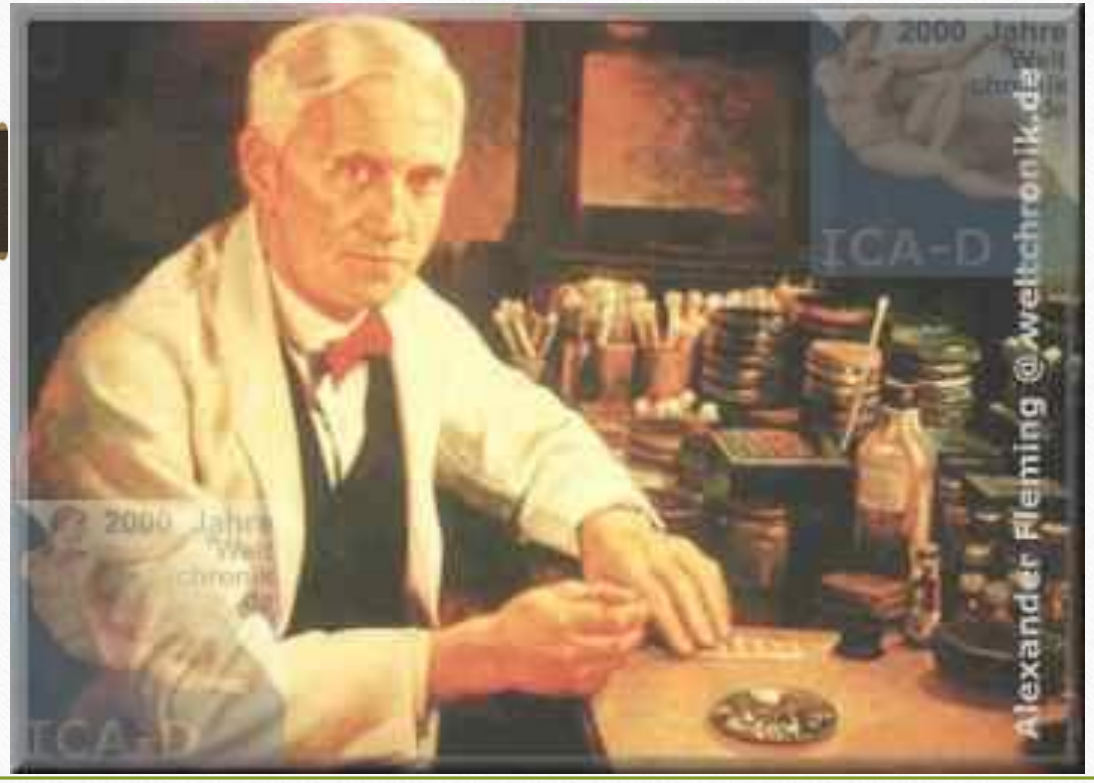
Antibiotics are fed to pigs to speed up growth and increase the efficiency of their digestion.

O sábio aviso de quem sabe…

- *"Existe claramente a necessidade de elevar esta problemática ao nível da decisão política porque constitui um problema económico e social e não só estritamente de saúde. Embora o compromisso dos políticos varie de região, deve existir um consenso global com uma abrangência planetária. Temos uma imperiosa necessidade de ter acesso não só à inovação tecnológica (nos âmbitos da prevenção, diagnóstico e tratamento), mas igualmente de inovação nos modelos de comercialização e fabrico. De preferência, deveríamos poder retroceder ao cenário onde existiam um confortável número de novos fármacos no "pipeline" e, simultaneamente, racionalidade na sua utilização. Para que isso possa acontecer, é vital envolver as faculdades de gestão, os economistas e ainda outros profissionais"*

… e a profetização de quem inventou!



- ***"Existe o perigo que alguém, por ignorância, possa vir a diminuir as o nº de tomas, a encurtar o tempo de tratamento, ou mesmo a reduzir as doses, expondo os microrganismos a quantidades não letais do antibiótico, e desse modo induzir a sua resistência".***

The risk/benefit of predicting a post-antibiotic era: Is the alarm working?

Tom Fowler,[1,2] David Walker,[3,b] and Sally C. Davies[3,a]

There have been concerns about antimicrobial resistance since the first widespread use of antibiotics in humans. More recently, this concern has grown and become the focus of clinical, scientific, and political activity. In part, the political interest is a consequence of publicizing a bleak picture of a post-antibiotic world. There are, however, dangers in using a discourse of fear. In this article, we discuss whether the evidence base is available to justify such claims and, more importantly, put this in the policy context with which it is used. Many governments now use a risk assessment approach to identify security concerns, based on reasonable worst-case scenarios. There is no doubt that for effective policy-based action to occur, antimicrobial resistance needs to be seen as a national and international security priority, particularly as the major cost of inaction will mostly be felt in the future. We conclude that presenting the evidence in a manner that is used to encourage prioritization of security policy is not only justified, it is essential to drive action in this area.

The increasing prevalence of hospital and community-acquired infections caused by multidrug-resistant (MDR) bacterial pathogens is limiting the options for effective antibiotic therapy. Moreover, this alarming spread of antimicrobial resistance has not been paralleled by the development of novel antimicrobials. Resistance to the scarce new antibiotics is also emerging. In this context, the rational use of older antibiotics could represent an alternative to the treatment of MDR bacterial pathogens. It would help to optimize the armamentarium of antibiotics in the way to preserve new antibiotics and avoid the prescription of molecules known to favor the spread of resistance (i.e., quinolones). Furthermore, in a global economical perspective, this could represent a useful public health orientation knowing that several of these cheapest "forgotten" antibiotics are not available in many countries. We will review here the successful treatment of MDR bacterial infections with the use of old antibiotics and discuss their place in current practice.

Abstract

Purpose of review—Increased emergence of bacterial resistance and the decline in newly developed antibiotics have necessitated the reintroduction of previously abandoned antimicrobial agents active against multidrug-resistant bacteria. Having never been subjected to contemporary drug development procedures, these 'old' antibiotics require redevelopment in order to optimize therapy. This review focuses on colistin as an exemplar of a successful redevelopment process and briefly discusses two other old antibiotics, fusidic acid and fosfomycin.

Recent findings—Redevelopment of colistin led to an improved understanding of its chemistry, pharmacokinetics and pharmacodynamics, enabling important steps towards optimizing its clinical use in different patient populations. A scientifically based dosing algorithm was developed for critically ill patients, including those with renal impairment. As nephrotoxicity is a dose-limiting adverse event of colistin, rational combination therapy with other antibiotics needs to be investigated.

Summary—The example of colistin demonstrated that state-of-the-art analytical, microbiological and pharmacokinetic/pharmacodynamic methods can facilitate optimized use of 'old' antibiotics in the clinic. Similar methods are now being applied to fosfomycin and fusidic acid in order to optimize therapy. To improve and preserve the usefulness of these antibiotics rational approaches for redevelopment need to be followed.

Conclusions

Education is not enough….

- Create an antimicrobial stewardship programm
- Make it multidisciplinary and efficient
- Costumize it to your service and centre
- Define a AMS physician champion as the leader and increase the interaction with microbiology
- Faclitate access
- Make it persuasive and pedagogical
- Assure accountability, defining goals and metrics in 3 domains: decrease antibiotic consumption, hospital acquired infections and antimicrobial resistance
- Communicate results to the staff
